## Abstract

In finite-state systems, if an LTL property is false, there is always a counterexample path (i.e. a witness) for it which is ultimately periodic (i.e. in a lasso-shaped form). When dealing with infinite-state systems, this is no longer the case. In this work, we address this issue by proposing an automatic approach that presents witnesses in an indirect way. The approach is based on two key insights. First, we leverage the notion of *well-founded funnel*, where a ranking function ensures that the states in the source set are guaranteed to inevitably reach the destination set. We show that, under suitable conditions, a sequence of funnels ensures the existence of a fair path. Second, we adopt a compositional approach to partition the original system into projections and to prove that they result in a non-empty under-approximation of the original system that only contains fair paths. Then, we propose an algorithm that, working in an abstract space induced by a set of predicates, identifies candidate funnels, proves their well-foundedness, and searches for a sequencing order. We experimentally evaluate the approach on examples taken from software, timed and hybrid systems, showing its wide applicability and expressiveness, with an implementation that outperforms various competitor tools.

---

## 1. Introduction

A well-known result in finite-state LTL model checking guarantees that the verification problem is decidable and, in particular, if a system does not satisfy a property there exists a witness in the form of a lasso-shaped fair path [3]. Model checking of LTL properties in infinite-state systems (e.g. software programs, 5 infinite-state transition systems, timed transition systems and hybrid systems) is an undecidable problem and there could be no lasso-shaped witness for the violation of some property.

A well-known instance of this problem is software (non)termination. In  
10 this context closed recurrence sets [4] are used to represent a witness for the  
nontermination of some software program. A closed recurrence set consists of  
a reachable set of states that is disjoint from the end states and inductive with  
respect to a left-total transition relation that underapproximates the transition  
relation of the program. The set represents at least one infinite execution for the  
15 program: (i) its reachability ensures that there is some finite execution of the  
program ending in some state within the set; (ii) since the set is also inductive,  
we know that no transition starting from within the set can reach a state outside  
of it and (iii) the left-total transition relation ensures that there always exists at  
least one successor state satisfying also the transition relation of the program.

20 In this work we are interested in representing *fair paths* of transition systems.  
Therefore, we do not look for any infinite execution, as in the nontermination  
case, but consider only those that visit a given set of states, called fair states,  
infinitely often. Recurrent sets are not sufficient, apart from some trivial cases,  
to conclude that every infinite execution visits some fair state infinitely often.  
25 Unless the set underapproximates the fair states, without additional informa-  
tion, we cannot conclude that the infinite executions described by the closed  
recurrence set are fair. For this reason, we split the closed recurrence set into  
two components  $S$  and  $D$  such that  $D$  is a subset of the fair states. The union  
of  $S$  and  $D$  must satisfy the same conditions described above for closed recur-  
30 rence sets and, in addition, the left-total transition relation must not allow for  
infinite sequences of  $S$  states: every state in  $S$  must reach a state in  $D$  in a  
finite number of steps.

When writing or reasoning on a transition system, a human usually restricts  
its attention to a component at-a-time and partitions the state-space into regions  
35 such that all states in a region exhibit similar features and the system visits  
the regions in some order. We propose an approach that mimics this kind  
of reasoning by splitting the monolithical problem described above into two  
orthogonal directions: by *segmenting* the infinite paths into finite paths and  
*decomposing* the system with respect to some partitioning of the symbols.

40 We segment the fair paths into a concatenation of finite paths: we split  $S$   
into multiple regions such that each region represents a set of finite paths that  
must eventually reach the following region. Notice that, while each path in a  
region must be finite, there might be no upper bound to their length: a region  
can represent an infinite number of finite paths with increasing lengths. We  
45 call each segment *funnel* and their concatenation representing the fair paths  
*funnel-loop*. In addition, we *decompose* the system by partitioning its symbols.  
Each component, called  $E$ -component (for existential component), describes the  
behaviour of a subset of the symbols while assuming some properties about the  
others. These properties represent the conditions that are necessary for this  
50 behaviour to be enabled and we need to prove that such conditions are ensured  
by some other component.

The main contributions of this work are the following: (i) we define an indi-  
rect representation of a non-empty set of fair paths for a transition system using  
funnel-loops; (ii) we show such representation to be both sound and relatively

55 complete; (iii) we partition the search problem in two orthogonal directions: segmentation and decomposition; (iv) we define a search procedure capable of identifying funnel-loops; (v) finally, we show the wide applicability and effectiveness of the proposed procedure via a prototype implementation.

This work is an extension and an integration of our previous works presented  
60 in [1] and [2]. In this article, we unify the two approaches in an integrated framework, in which the search for a funnel-loop witnessing the falsification of a given property (first introduced in [2]) can be decomposed by using the  $E$ -component concept of [1] extended with ranking functions.<sup>1</sup> Moreover, we enrich the results of [2] by a relative-completeness theorem for the representation  
65 of fair paths as funnel-loops, and an encoding for the search problem of a funnel-loop in existentially-quantified constrained Horn clauses. Finally, we provide all the proofs of our results and we revised our experimental evaluation considering also an additional competitor tool.<sup>2</sup>

The paper is structured as follows. In Section 2 we describe the notation  
70 and introduce the constructs we use in the following sections. In Section 3 we provide an overview of the proposed approach. In Section 4 we introduce a running example that we will use to illustrate our procedures. In Section 5 we define funnels and funnel-loops, prove their properties and show how they can be used to identify fair paths for a fair transition system. In Section 6 we  
75 define  $E$ -components, their composition and projection operators and show the relationship between  $E$ -components and funnel-loops. In Section 7 we present an algorithm to search for a funnel-loop describing a non-empty set of fair paths of a fair transition system. In Section 8 we discuss the related work. In Section 9 we briefly describe some implementation details of our prototype and  
80 then discuss our experimental results. In Section 10 we draw some conclusions and outline the directions for future work.

## 2. Background

We work in the setting of SMT, with the theory of quantified mixed integer-real nonlinear arithmetic. We assume the standard notions of interpretation,  
85 model, satisfiability, validity and logical consequence.

### 2.1. Symbols, formulae, implicants and entailment

Given a set of symbols  $V$ , we use  $V' \doteq \{v' | v \in V\}$  for the set containing the primed version of the symbols. We write  $\phi(V)$  for a Boolean formula over the symbols in  $V$  and  $\phi(V, V')$  for a Boolean formula or relation over  $V \cup V'$ .  
90 When clear from the context we will omit the set of symbols and simply write  $\phi$ ,  $\psi$  and  $\phi'$  for  $\phi(V)$ ,  $\psi(V, V')$  and  $\phi(V')$  respectively. We say that a formula  $\phi(V, V')$  underapproximates a formula  $\psi(V, V')$  iff every time  $\phi$  holds then also

---

<sup>1</sup> $E$ -components (without ranking functions) were called  $AG$ -skeletons in [1].

<sup>2</sup>In order to aid readability, some of the more technical proofs are presented in appendix.

$\psi$  must hold, hence  $\phi \rightarrow \psi$  is valid. We use  $\top$  and  $\perp$  in formulae to represent respectively the true and false Boolean constants.

95 We denote with  $\mathbf{v}$  a total assignment over  $V$ , i.e. a state. Given a formula  $\phi(V)$  we write  $\phi(\mathbf{v})$  for the evaluation of  $\phi$  obtained by replacing every symbol in  $V$  with its corresponding assignment in  $\mathbf{v}$  and  $\phi(\mathbf{v}')$  for the evaluation of  $\phi$  where every symbol  $v \in V$  is replaced by the assignment of  $v'$  in  $\mathbf{v}'$ . We overload the  $\models$  symbol: when  $\phi$  and  $\psi$  are SMT formulae, then  $\phi \models \psi$  stands  
100 for entailment in SMT; when  $M$  is a fair transition system and  $\psi$  is a linear temporal property, then  $M \models \psi$  is to be interpreted with the LTL semantics.

Finally, if  $\psi$  is a quantifier-free SMT formula and  $\phi$  is a conjunction of (a subset of) the atoms of  $\psi$ , then  $\phi$  is an implicant of  $\psi$  iff  $\phi \models \psi$ .

## 2.2. Well-founded relations and ranking functions

105 A binary relation  $\rho \subseteq Q \times Q$  is well-founded if every non-empty subset  $U \subseteq Q$  has a minimal element with respect to  $\rho$ , i.e. there is  $m \in U$  such that no  $u \in U$  satisfies  $\rho(u, m)$ . Given a relation  $\phi(V, V')$ , a ranking function  $\text{RF}(V)$  is a function from the assignments to the symbols  $V$  to some set  $Q$ , such that the relation  $< \doteq \{ \langle \text{RF}(\mathbf{v}_0), \text{RF}(\mathbf{v}'_1) \rangle \mid \mathbf{v}_0, \mathbf{v}'_1 \models \phi \}$  is well-  
110 founded and we call  $\mathbf{0}$  its minimal element. Given a set of ranking functions  $\{\text{RF}_i\}_{i=0}^n$ , we define their sum as  $\text{RF} \doteq \sum_{i=0}^n \text{RF}_i \doteq \langle \text{RF}_0, \dots, \text{RF}_n \rangle$ .  $\text{RF}$  is a ranking function with minimal element  $\mathbf{0} \doteq \langle \mathbf{0}_0, \dots, \mathbf{0}_n \rangle$  and comparison operator  $< \doteq \{ \langle \mathbf{v}_0, \mathbf{v}_1 \rangle \mid (\bigwedge_{i=0}^n \text{RF}_i(\mathbf{v}_0) \leq_i \text{RF}_i(\mathbf{v}_1)) \wedge (\bigvee_{i=0}^n \text{RF}_i(\mathbf{v}_0) <_i \text{RF}_i(\mathbf{v}_1)) \}$  where  $<_i$  is the well-founded relation associated with  $\text{RF}_i$  and  $\leq_i$  is a shortcut for the  
115 disjunction of  $<_i$  and the equality.

## 2.3. LTL model checking

A symbolic fair transition system  $M$  is a tuple  $\langle V, I(V), T(V, V'), F(V) \rangle$ , where  $V$  is the set of state variables;  $I$  and  $F$  denote respectively the initial and fair states; and  $T$  represents the transitions where  $V'$  refers to the next  
120 state variables. A path or trace of  $M$  is a finite or infinite sequence of states  $\mathbf{v}_0, \mathbf{v}_1, \dots$ , such that  $\mathbf{v}_0 \models I$  and  $\mathbf{v}_i, \mathbf{v}'_{i+1} \models T$  for all  $i$ , where  $\mathbf{v}'_i$  assigns to every symbol  $v' \in V'$  the same value assigned by  $\mathbf{v}_i$  to  $v$ . A state  $\mathbf{v}$  is reachable in  $M$  if there is a finite path of  $M$  ending in  $\mathbf{v}$ . Given a formula  $\phi(V)$  we write  $M \rightsquigarrow \phi$  iff there exists a finite path in  $M$  ending in a state  $\mathbf{v}$  such that  $\mathbf{v} \models \phi$ .

125 A path  $\mathbf{v}_0, \mathbf{v}_1, \dots$  of  $M$  is fair iff for each  $i$  there exists  $j > i$  such that  $\mathbf{v}_j \models F$  and the language of  $M$ , written  $\mathcal{L}(M)$ , is the set of all fair paths of  $M$ .<sup>3</sup> We also assume the standard notions of temporal logic model checking, using the usual definitions of **U**, **G**, **F** for the “until”, “always” and “eventually” temporal operators (LTL [5]): for a LTL property  $\varphi$  we write  $M \models \varphi$  iff  $\varphi$   
130 holds in every path  $\pi \in \mathcal{L}(M)$ . Given a fair transition system  $M$ , we are interested in the problem of deciding whether  $M$  admits at least one fair path (i.e.  $\mathcal{L}(M) \neq \emptyset$ ). Notice that the existential LTL model checking problem, i.e.

<sup>3</sup>Note that fair paths are necessarily infinite.

the problem of deciding whether a system  $M \doteq \langle V, I, T, \top \rangle$  admits at least a path that satisfies a given LTL formula  $\varphi$ , can be reduced to checking for the existence of a fair path in the fair transition system  $M \times M_\varphi \doteq \langle V \cup V_\varphi, I \wedge I_\varphi, T \wedge T_\varphi, F_\varphi \rangle$ ,  
 135 where  $M_\varphi \doteq \langle V_\varphi, I_\varphi, T_\varphi, F_\varphi \rangle$  is a symbolic encoding of an automaton accepting the language of  $\varphi$  [6], which can be obtained, for example, with the procedure of [7]. In addition, in finite-state systems liveness-to-safety [8] allows the reduction of such problem to the falsification of safety properties.

140 A standard technique for the analysis of infinite-state systems is predicate abstraction [9]. Predicate abstraction partitions the state space according to the equivalence relation induced by a set of predicates. Given a finite set of predicates, it defines a finite set of abstract states each of which corresponds to a total truth assignment of such predicates. An abstract state corresponds  
 145 to a possibly infinite set of concrete states: all states that agree on the truth assignments of the predicates. Implicit abstraction is an approach to avoid the explicit computation of the abstract space. Implicit abstraction has been used, e.g. in [10], in combination with liveness-to-safety to identify abstract fair loops for an infinite-state system in the abstract space. However, in general, there  
 150 might not exist a fair path in the concrete system corresponding to the abstract one.

Finally, we consider also timed systems such as timed automata [11], timed transition systems [12] and hybrid systems [13]. Timed systems are infinite-state transition systems in which each state is associated with a real-valued time and  
 155 transitions may cause time to elapse. An LTL property holds in such systems iff it holds in all its *non-Zeno* paths. A path is *non-Zeno* iff the sequence of time points associated to its states is diverging (i.e. there is no upper bound on the value of time along the path).<sup>4</sup>

### 3. Overview of the approach

160 Our objective is to define a representation of and a search procedure for a non-empty set of fair paths for a transition system. We split the representation of the fair paths along two orthogonal directions. We first *segment* them into finite sequences of elements each of which represents a set of finite paths. Then, we *decompose* the fair transition system with respect to a partitioning of its  
 165 symbols; in this case each component represents a set of infinite behaviours for a subset of the symbols. Therefore, the search problem is reduced to the problem of identifying an appropriate set of components such that their composition is a witness for some fair path in the transition system.

#### 3.1. Segmentation: funnels

170 We *segment* fair paths into a sequence of elements called *funnels* that, like actual funnels, take items from a source and constrain them to follow a path

---

<sup>4</sup>As for fair paths, also non-Zeno paths are necessarily infinite.

Figure 1: Funnels combined into chain forming a funnel-loop.

leading to a destination. Funnels are compact witnesses for universal and existential reachability [14]: each funnel characterizes a set of finite paths, each starting from the source region, remaining in it for a bounded number of steps, and eventually ending in the destination region. Funnels are concatenated in chains such that the destination region of a funnel is contained in the source region of the following one. Funnel-loops are chains of funnels in which the destination region of the last funnel is included in the source region of first one. An example of funnel-loop composed of 6 funnels is depicted in Fig. 1. Funnel-loops describe a loop over the regions of the corresponding funnels and we ensure the fairness of such loop by requiring at least one of the destination regions to contain only fair states. Therefore, we propose to represent witnesses for fair paths of transition systems by composing a finite number of reachability witnesses. Sec. 5 formally presents funnel-loops and shows them to be a sound (Th. 1) and complete (Th. 2) representation of fair paths.

### 3.2. Decomposition: existential components

We *decompose* a fair transition system with respect to a partitioning of its symbols. For each subset of the symbols, we identify components, called *E*-components (for *existential components*), that represent their behaviour with respect to a sequence of regions. *E*-components distinguish three kinds of transitions between their regions and all states in the same region must exhibit transitions of the same kind. In this sense, the regions of an *E*-component group states with similar behaviour. We define two operators over these structures. The first operation, called *projection*, shrinks the set of paths described by an *E*-component by considering only a subset of its regions. The second operation, called *composition*, defines how *E*-components can be composed to obtain a description of the behaviour of a larger set of symbols: the union of the symbols of the composed elements. In this setting we represent fair paths as the composition and projection of a finite set of *E*-components.

Sec. 6 formally defines *E*-components and the two operators, while Theorems 3 and 6 highlight the relationship between funnel-loops and *E*-components. In more detail, Th. 3 shows that a funnel-loop also defines a corresponding *E*-component and, viceversa, Th. 6 details the conditions under which an

*E*-component corresponds to a funnel-loop proving the existence of at least one  
205 fair path for some fair transition system.

### 3.3. Search procedure

We propose a fully-automated procedure that, given a fair transition system  
and a possibly empty set of *E*-components, searches for a funnel-loop containing  
at least one and only fair paths (Alg. 1). We propose to search for a funnel-  
210 loop by enumerating candidate fair loops of the transition system (Alg. 2). We  
consider loops such that the first and last state of the path are in the same  
abstract state with respect to a set of abstraction predicates. For every such  
candidate loop we compute a sequence of regions and transitions containing it  
(Alg. 3). Then, we search for a funnel-loop corresponding to a strengthening of  
215 the sequence of regions and transitions such that all required hypotheses are met  
(Sec. 7.4). If the search succeeds we return the obtained funnel-loop, otherwise  
we continue by analysing the next candidate fair loop.

The procedure, described in Sec. 7, is fully-automated and deals with an  
undecidable problem. Therefore, there will always exist some inputs for which  
220 it fails to provide an answer and, from a more practical perspective, inputs for  
which it takes a very long time to provide an answer. For this reason, the pro-  
cedure is capable of exploiting some additional information in the form of a set  
of *E*-components. If some *E*-components are provided, the procedure identifies  
candidate fair loops that are also a path for some composition and projection of  
225 a subset of the *E*-components. It then tries to identify the funnel-loop that cor-  
responds to an *E*-component describing the behaviour for the missing symbols:  
it completes the *E*-component with a transition relation over the remaining  
symbols such that all assumptions are met.

## 4. Running example

230 We now introduce a simple LTL verification problem on a software program  
that will be used as running example throughout this work.

Consider the simple program shown in Fig. 2, where NONDET is a function  
that nondeterministically selects a value from the set provided as input. Our

```
1: int  $x \leftarrow \text{NONDET}(\mathbb{Z})$   
2: real  $y \leftarrow \text{NONDET}(\mathbb{R})$   
3: while  $x^2 \geq xy$  do  
4:    $y \leftarrow \text{NONDET}(\mathbb{R})$   
5:    $x \leftarrow x + 1$   
6: end while
```

Figure 2: Running example.

objective is to check whether in every infinite execution of such program the

235 value of  $y$  will eventually remain always positive or always negative. This statement can be written in LTL as  $(\mathbf{FG}y \geq 0) \vee (\mathbf{FG}y \leq 0)$ . Intuitively, any counterexample to such specification must be a nonterminating execution of the program in which both  $y > 0$  and  $y < 0$  hold infinitely often.

We encode the software program as an infinite-state transition system using an additional variable  $pc$  to model the program counter. Then, we employ the reduction from LTL model checking to the existence of a fair path. The resulting infinite-state transition system is  $Ex \doteq \langle \{x, y, pc, f_0, f_1\}, pc = 3, T, f_0 \wedge f_1 \rangle$ , where  $pc$  and  $x$  are two integer variables,  $y$  is a real variable,  $f_0$  and  $f_1$  are two Boolean symbols (introduced by the reduction to keep track of the fairness conditions  $y > 0$  and  $y < 0$ ) and the transition relation is defined as follows:

$$\begin{aligned}
T \doteq & (pc = 3 \rightarrow (x^2 \geq xy \wedge pc' = 4 \wedge x' = x \wedge y' = y)) \wedge \\
& (pc = 4 \rightarrow (pc' = 5 \wedge x' = x)) \wedge \\
& (pc = 5 \rightarrow (pc' = 3 \wedge x' = x + 1 \wedge y' = y)) \wedge \\
& ((f_0 \wedge f_1) \rightarrow (\neg f'_0 \wedge \neg f'_1)) \wedge \\
& (f'_0 \rightarrow (f_0 \vee y > 0)) \wedge (f'_1 \rightarrow (f_1 \vee y < 0)).
\end{aligned}$$

240 The first three lines encode the transition relation of the program. Notice that every state such that  $pc = 3$  and  $\neg(x^2 \geq xy)$  hold is a deadlock for  $Ex$ . In all such cases, the transition relation admits no successor state. Finally, the last two lines of the formula ensure that in every execution in which  $f_0 \wedge f_1$  holds infinitely often also  $y > 0$  and  $y < 0$  hold infinitely often.

## 5. Segmenting paths with funnels

Figure 3: Funnels combined into chain forming a funnel-loop.

245 In this section, first we formally define *funnels* and their concatenation into funnel-loops; then we provide a set of sufficient conditions for a funnel-loop to represent at least one fair path of a transition system and show that if such a fair path exists then also a corresponding funnel-loop must exist.

### 5.1. Funnels

250 Funnels *segment* fair paths into finite subpaths. Given a set of symbols  $V$ , a funnel is a 4-tuple  $\langle S(V), T(V, V'), D(V), RF(V) \rangle$ .  $S$  and  $D$  are formulae representing respectively the source and destination regions,  $T$  is the transition

relation and  $\text{RF}$  is a ranking function for  $S$  with respect to the transition relation  $T$ . Intuitively, this structure represents a terminating loop over  $S$  where  $D$  are  
 255 the end states of the loop. Depending on the shape of the ranking function, the loop might correspond to a simple loop or to more complex termination arguments such as nested loops. Every path through the funnel starts from a state in  $S$  and follows the relation  $T$  such that it remains in  $S$  while the ranking function  $\text{RF}$  is greater than the minimal element  $\mathbf{0}$  and, finally, it reaches a  
 260 state in  $D$  when  $\text{RF}$  is  $\mathbf{0}$ . If we consider a trivial ranking function that is always equal to the minimal element  $\mathbf{0}$  the 4-tuple simply asserts that every state in  $S$  is mapped into  $D$  by a single transition  $T$ .

**Definition 1 (Funnel).** *Given a set of symbols  $V$ , a funnel is defined as the 4-tuple*

$$fnl \doteq \langle S(V), T(V, V'), D(V), \text{RF}(V) \rangle$$

265 where:  $\text{RF}$  is a ranking function with minimal element  $\mathbf{0}$  and  $S$ ,  $D$  and  $T$  are formulae representing respectively the source region, destination region and transition relation of  $fnl$ . Every funnel satisfies the following hypotheses.

**F.1** *The transition relation is left-total relative to the source region.*

$$\forall V \exists V' : S \rightarrow T$$

270 **F.2** *Every funnel keeps iterating on the source region as long as its ranking function is greater than the minimal element.*

$$\forall V, V' : (S \wedge \mathbf{0} < \text{RF} \wedge T) \rightarrow S'$$

**F.3** *Every step from the source region decreases the ranking function.*

$$\forall V, V' : (S \wedge \mathbf{0} < \text{RF} \wedge T) \rightarrow \text{RF}' < \text{RF}$$

**F.4** *Once the ranking function is equal to  $\mathbf{0}$  the funnel reaches its destination region.*

$$\forall V, V' : (S \wedge \text{RF} = \mathbf{0} \wedge T) \rightarrow D'$$

Given a funnel  $fnl_i$  we write  $S_i$ ,  $T_i$ ,  $D_i$  and  $\text{RF}_i$  to refer to its components.  
 275 We define the transition system corresponding to a funnel  $fnl \doteq \langle S, T, D, \text{RF} \rangle$  over symbols  $V$  as  $M_{fnl} \doteq \langle V, S, (\neg D \wedge T) \vee (D \wedge D'), \top \rangle$ . We refer to the paths through a funnel  $fnl$  meaning the finite paths of the corresponding transition system that end in  $D$  and write  $fnl \models \phi$  meaning that  $\phi$  holds in every path in  $\mathcal{L}(M_{fnl})$ . Notice that the paths through a funnel are all finite and each of them  
 280 is a prefix of some path in  $\mathcal{L}(M_{fnl})$ . From the definition it easily follows that every funnel  $fnl$  satisfies the following:

$$fnl \models S \mathbf{U} D$$

## 5.2. Funnel-loops

We define a funnel-loop as a chain of funnels  $[fnl_i]_{i=0}^{n-1}$  such that the destination region of each funnel is included in the source region of the following one and the destination region of the last funnel is included in the source region of the first one.

**Definition 2 (Funnel-loop).** *A sequence of  $n \geq 1$  funnels  $[fnl_i]_{i=0}^{n-1}$  over symbols  $V$  is a funnel-loop iff the following hold.*

**FL.1** *The destination region of a funnel is included in the source region of the following funnel.*

$$\forall 0 \leq i < n - 1, V : D_i \rightarrow S_{i+1}$$

**FL.2** *The destination region of the last funnel  $D_{n-1}$  is contained in the source region of the first funnel  $S_0$ .*

$$\forall V : D_{n-1} \rightarrow S_0$$

We define the paths through a funnel-loop  $floop$ ,  $\mathcal{L}(floop)$ , as the infinite paths obtained by infinite concatenation of the paths through the funnels in the corresponding chain and write  $floop \models \phi$  meaning that  $\phi$  holds in all such paths. For every funnel different from the last one, Hyp. FL.1 ensures that we can extend every path of such funnel, ending in its destination region, by following the transition relation of the next funnel. Therefore, every path starting in any source region will eventually reach the destination region of the last funnel:

$$floop \models \left( \bigvee_{i=0}^{n-1} S_i \right) \mathbf{U} D_{n-1}$$

By Hyp. FL.2 every time we reach the destination region of the last funnel associated with  $floop$  we are also in the source region of the first funnel. Therefore, we can extend the execution by appending another finite number of steps: a finite path starting from  $S_0$  and ending in the last destination region  $D_{n-1}$ . We can do this infinitely many times obtaining infinite paths.

$$floop \models \mathbf{G} \left( \left( \bigvee_{i=0}^{n-1} S_i \right) \mathbf{U} D_{n-1} \right)$$

The definition of funnel-loop allows for regions with non-empty intersections. This eases the construction of the structure in practical cases. It is possible to consider one funnel at a time and then chain them simply by checking the inclusion of each destination into the corresponding source region. However, for every funnel-loop there exists one with pairwise-disjoint regions that has the same language projected over the common variables.<sup>5</sup> For this reason, when

---

<sup>5</sup>See [Appendix B.1](#) for a proof.

proving statements about the language of these structures, we assume without loss of generality that the regions of every funnel in the funnel-loops are pairwise-disjoint.

We propose to identify a non-empty set of fair paths for a transition system  $M$  as a funnel-loop *floop*; every path through *floop* must correspond to an infinite fair execution of  $M$ . The totality of the transition relation of each funnel (F.1) and their chaining (FL.1, FL.2) ensure that all the paths in  $\mathcal{L}(\textit{floop})$  are infinite. We need such paths to be fair paths, hence they must visit the fairness condition infinitely often. By construction of *floop* we know that every path goes through each  $S_i$  and each  $D_i$  infinitely many times. Since by FL.1 and FL.2 for every source region  $S_i$ , there exists a destination region  $D_j$  that is contained in it, it is sufficient to require one of the destination regions to contain only fair states. Without loss of generality we assume such a region to be the last one. These conditions ensure that *floop* represents a set of fair paths of  $M$ . However, such set might be empty or non-reachable in  $M$ . Therefore, we finally require the union of the source regions to contain at least one state reachable in  $M$ . The existence of such state is sufficient to conclude non-emptiness of  $\mathcal{L}(\textit{floop})$  because the transition relation of each funnel always allows for a successor state (F.1) and, by induction, this ensures that every region and the language of *floop* are not empty. Th. 1 shows that these requirements are sufficient for a funnel-loop to prove the existence of a fair path in  $M$  and Th. 2 shows that if  $M$  admits a fair path then there exists a funnel-loop of length one for  $M$ . Therefore, funnel-loops composed of a single funnel are expressive enough to represent any fair path. However, funnel-loops of greater length lead to a description easier to understand for a person and, in addition, could simplify the search procedure: we might not need to consider complex disjunctive representations of the regions, ranking functions and transition relations.

**Theorem 1.** *Let  $M = \langle V, I^M, T^M, F^M \rangle$  be a fair transition system. Let *floop* be a funnel-loop of length  $n$  over the symbols  $V$  and funnels  $[fnl_i]_{i=0}^{n-1}$  such that:*

**FF.1** *There is at least one state in the union of the source regions of *floop* that is reachable in  $M$ :*

$$M \rightsquigarrow \bigvee_{i=0}^{n-1} S_i$$

**FF.2** *The destination region of the last funnel contains only fair states of  $M$ .*

$$\forall V : D_{n-1} \rightarrow F^M$$

**FF.3** *Every transition of every funnel underapproximates the transition relation of  $M$ . For every funnel  $fnl_i$  in  $[fnl_i]_{i=0}^{n-1}$ :*

$$\forall V, V' : S_i \wedge T_i \rightarrow T^M$$

*Then  $M$  admits at least one fair path.*

*Proof.* We first prove that every path in  $\mathcal{L}(floop)$  is infinite. Then we prove that every such path is fair with respect to the fairness condition  $F^M$  and that every step in every such path satisfies the transition relation  $T^M$ . Finally, we prove that  $\mathcal{L}(floop)$  allows for at least one path which is a suffix of some path of  $M$ .

- *Every path in  $\mathcal{L}(floop)$  is infinite.* Consider a funnel  $fnl \doteq \langle S, T, D, \text{RF} \rangle$  in  $floop$ . Hyp. **F.1** ensures that its transition relation  $T$  allows for a successor state for every state in  $S$ . Hyp. **F.2** ensures that every path of  $fnl$  remains in  $S$  while  $\mathbf{0} < \text{RF}$ . Hyp. **F.3** ensures that every such path will eventually reach a state in  $S \wedge \text{RF} = \mathbf{0}$ . Hyp. **F.4** ensures that every state in such region in one  $T$  step reaches a state in  $D$ . Therefore, every path starting from the source region  $S$  of each funnel can be extended until it reaches its destination region  $D$ . If  $fnl_{i-1}$  has a successor  $fnl_i$  in  $floop$ , by Hyp. **FL.1** the destination region  $D_{i-1}$  is included in  $S_i$ : every state in  $D_{i-1}$  is also in  $S_i$ . Therefore, the concatenation of  $fnl_{i-1}$  and  $fnl_i$  allows to extend every path starting from either  $S_{i-1}$  or  $S_i$  until it reaches  $D_i$ . By induction this shows that the funnel chain allows the extension of every path starting from the union of the source regions until it reaches the last destination region:

$$floop \models \left( \bigvee_{i=0}^{n-1} S_i \right) \cup D_{n-1}$$

Hyp. **FL.2** requires the last destination region  $D_{n-1}$  to be a subset of the first source region  $S_0$ . As stated above, we can extend every path starting in every region until it reaches  $D_{n-1}$ , hence from  $S_0$  we reach  $D_{n-1}$  again in a finite number of steps and at least one. Therefore, since we can extend each path of a finite non-zero number of steps infinitely many times every path in  $\mathcal{L}(floop)$  is infinite.

- *Every path in  $\mathcal{L}(floop)$  visits  $F^M$  infinitely often.* Hyp. **FF.2** ensures that  $D_{n-1}$  underapproximates the fair states  $F^M$ . We have already shown above that every path of  $floop$  reaches a state in  $D_{n-1}$  infinitely often. Therefore, such paths visit  $F^M$  infinitely often.
- *Every step of every path in  $\mathcal{L}(floop)$  satisfies  $T^M$ .* Every step of every path in  $\mathcal{L}(floop)$ , by definition, corresponds to a transition of some funnel  $fnl$ . By hypotheses **F.2**, **F.4**, **FL.1** and **FL.2** every such path remains within the union of the regions and visits them following the order of the funnels. Therefore, every transition in every path of  $floop$  must satisfy  $S \wedge T$  for some funnel  $fnl$  in the sequence. Hyp. **FF.3** ensures that if  $S \wedge T$  holds that also  $T^M$  is true. Therefore every step of every path of  $floop$  is also a step of  $M$ .
- *$\mathcal{L}(floop)$  allows for at least one path which is a suffix of some path of  $M$ .* Hyp. **FF.1** ensures that there exists a finite path  $\pi_{pref}$  of  $M$  starting in

$I^M$  and ending in some state  $\mathbf{v}$  such that  $\mathbf{v} \models \bigvee_{i=0}^{n-1} S_i$ . Therefore,  $\mathbf{v}$  must be in  $S_i$  for some  $0 \leq i < n$ . Then, in *floop* we can extend  $\mathbf{v}$  to an infinite fair path  $\pi_{suf}$  starting in  $\mathbf{v}$ . As shown above every step of  $\pi_{suf}$  satisfies the transition relation of  $M$  and visits the fairness condition  $F^M$  infinitely often. The concatenation  $\pi$  of  $\pi_{pref}$  and  $\pi_{suf}$  without repetition of  $\mathbf{v}$ , starts from a state in  $I^M$ , every steps satisfies  $T^M$  and visits  $F^M$  infinitely often. Therefore,  $\pi$  is a fair path for  $M$ :  $\pi \in \mathcal{L}(M)$ .

□

Th. 2 ensures that if a transition system admits a fair path then there exists a corresponding funnel-loop, provided it is possible to represent the states in the path as formulae and, in particular, we are interested in finite formulae. In finite-state systems this is always the case: every set of states is finite and can be represented as a finite quantifier-free formula (e.g. the disjunction of the assignments in the set). However, this might not be the case in infinite-state systems: there might be an infinite set of states which cannot be represented by a finite formula. Therefore, the following theorem guarantees completeness relative to the expressiveness of the logic used to represent the regions and the transition relation of the funnel. Notice that the existence of a finite representation is not the only source of incompleteness. In fact, the existence of a finite formula does not imply the existence of a complete procedure capable of finding it. We remark that we are dealing with an undecidable problem, hence there exists no procedure to solve it that is both sound and complete.

**Theorem 2.** *If a fair transition system  $M$  admits at least one fair path, then there exists a funnel-loop *floop* of length 1 for  $M$ . However, the existence of one representable via finite formulae depends on the expressiveness of the considered logic.*

*Proof.* In the following we will define a predicate  $\phi(V)$  as the set of assignments  $\mathbf{v}$  such that  $\mathbf{v} \models \phi$ , meaning that  $\phi(V)$  is a formula equivalent to the disjunction of the assignments in the set. Notice that there might be no finite representation of  $\phi$ .

Let  $M \doteq \langle V, I^M, T^M, F^M \rangle$  and, by hypothesis, there exists a fair path  $\pi$  in  $\mathcal{L}(M)$ . Without loss of generality we assume that  $\pi$  visits every state at most once. If this is not the case, to obtain a fair path satisfying the hypothesis, it is sufficient to add an additional integer symbol whose assignment increases by one at every transition. In more detail, consider the fair transition system  $\langle V \cup c, I^M \wedge c = 0, T^M \wedge c' = c + 1, F^M \rangle$ , if  $\pi$  is a fair path of  $M$  then, we can obtain a fair path for the modified system by extending the assignment of every state of  $\pi$  such that  $c = 0$  in the first state and in all other states assign to  $c$  the assignment of the previous state plus 1.

Let *floop* be a funnel-loop of length 1, and let its funnel be  $fnl \doteq \langle S, T, D, RF \rangle$ . We define the components of *fnl* as follows:

- $S$  contains all and only states of  $\pi$ .

$$S \doteq \{ \mathbf{v} \mid \mathbf{v} \in \pi \}$$

- $D$  contains all and only the fair states of  $\pi$ .

$$D \doteq \{\mathbf{v} \mid \mathbf{v} \in \pi \wedge F^M(\mathbf{v})\}$$

- $T$  is a relation containing all pairs of state  $\langle \mathbf{v}, \mathbf{v}' \rangle$  such that  $\mathbf{v}'$  is the successor state of  $\mathbf{v}$  in  $\pi$ .

$$T \doteq \{\langle \mathbf{v}, \mathbf{v}' \rangle \mid \langle \mathbf{v}, \mathbf{v}' \rangle \in \pi\}$$

- RF associates to every state in  $\pi$  the number of steps required to reach the next fair state in  $\pi$  minus 1.

$$\forall k > 0, \forall V_1, \dots, V_k : \text{RF}(V_1) = k - 1 \leftrightarrow \left( \bigwedge_{i=1}^{k-1} T(V_i, V_{i+1}) \right) \rightarrow F^M(V_k)$$

This is well-defined since each state appears only once in  $\pi$  and by construction  $T$  allows for a single successor for each state. In addition,  $\pi$  is a fair path by hypothesis, hence there can be at most a finite number of non-fair states between every pair of fair states.

We now show that  $fnl$  satisfies all hypotheses of Def. 1.

**F.1**  $\pi$  is an infinite sequence of states, all states of  $\pi$  are in  $S$  and each pair of subsequent states of  $\pi$  is in  $T$ . Therefore,  $T$  must be left-total with respect to  $S$  and Hyp. F.1 holds.

**F.2** By construction  $S$  contains all states of  $\pi$  and  $T$  is a relation between states of  $\pi$ . Therefore,  $S$  is an inductive invariant for  $T$  and Hyp. F.2 holds.

**F.3** By construction, RF is greater than 0 in all states that require more than 1 transition to reach a fair state and  $T$  is such that it brings all such states 1 step closer to the next fair state in  $\pi$ . Therefore,  $S(V) \wedge 0 < \text{RF}(V) \wedge T(V, V') \rightarrow \text{RF}(V) = \text{RF}(V') + 1$ , which implies Hyp. F.3.

**F.4** By construction RF assigns the minimal value 0 to the states that reach a fair state in 1 step. Therefore, Hyp. F.4 holds.

We now show that  $fnl$  corresponds to a funnel-loop *floop* of length one: it satisfies all hypotheses of Def. 2.

**FL.1** *floop* contains a single funnel, hence Hyp. FL.1 trivially holds.

**FL.2** By construction  $S$  contains all states of  $\pi$  while  $D$  contains the subset of states of  $\pi$  that are also fair. Therefore,  $D \rightarrow S$  is valid and Hyp. FL.2 holds.

Finally, *floop* represents fair paths of  $M$ : it satisfies all hypotheses of Th. 1

FF.1  $\pi$  is a path of  $M$ , hence its first state is an initial state of  $M$ . All states of  $\pi$  are in  $S$ . Therefore,  $S$  contains at least 1 initial state of  $M$  and Hyp. FF.1 holds.

460 FF.2 The last destination region of *floop* is  $D$ . By construction  $D$  contains only fair states, hence Hyp. FF.2 holds.

FF.3  $\pi$  is a path of  $M$ . Therefore, every pair of states  $\langle \mathbf{v}, \mathbf{v}' \rangle$  such that  $\mathbf{v}'$  is the successor state of  $\mathbf{v}$  in  $\pi$ , must also be in the relation  $T^M$ . By construction  $T$  contains only such pairs, hence  $T \rightarrow T^M$  is valid and Hyp. FF.3 holds.

### 5.3. Example

We now define two funnel-loops, of length respectively 6 and 1, for the running example introduced in Sec. 4. Both funnel-loops are sufficient to conclude the existence of a fair path for the fair transition system *Ex* we defined in Sec. 4.  
 470 Here we simply recall that the system has 5 state variables  $V \doteq \{x, y, pc, f_0, f_1\}$  and that the fair states are all the states where  $f_0 \wedge f_1$  holds.

Figure 4: funnel-loop *floop* of length 6.

We first describe the funnel-loop  $floop \doteq [fnl_i]_{i=0}^5$  depicted in Fig. 4. The figure reports the source regions and transition relations of each funnel. The transitions in the figure report only the constraints for  $x$  and  $y$ , while the ones for  $pc$ ,  $f_0$  and  $f_1$  can be trivially inferred by the assignments in the regions. More formally, each funnel  $fnl_i$  is the tuple  $\langle S_i, T_i, D_i, RF_i \rangle$ . We define each ranking function such that it is always equal to its minimal element,  $\forall V : RF_i(V) = \mathbf{0}$ , and each destination region as the corresponding source region,  $D_i \doteq S_{(i+1)\%6}$ . We define the remaining components, source regions and transition relations, as follows.  
 480

0. The first funnel  $fnl_0$  represents the step from location 3 to location 4 of Fig. 2. In  $S_0$  both  $f_0$  and  $f_1$  are true, hence  $S_0$  contains only fair states and also  $D_5 \doteq S_0$  does. Notice that  $x \geq y \wedge y > 0$  implies  $x^2 \geq xy$ . Therefore, the condition of the while loop is satisfied.

$$\begin{aligned} S_0 &\doteq pc = 3 \wedge x \geq y \wedge y > 0 \wedge f_0 \wedge f_1 \\ T_0 &\doteq pc' = 4 \wedge x' = x \wedge y' = y \wedge \neg f'_0 \wedge \neg f'_1 \end{aligned}$$

1. The second funnel  $fnl_1$  performs the step from  $pc = 4$  to  $pc = 5$ . In this step, the program of Fig. 2 assigns a nondeterministic value to  $y$ . The funnel underapproximates this transition by always assigning to  $y$  the opposite of its current value. In addition, since  $y > 0$  in  $S_1$ , the transition relation assigns  $f'_0$  to true.

$$\begin{aligned} S_1 &\doteq pc = 4 \wedge x \geq y \wedge y > 0 \wedge \neg f_0 \wedge \neg f_1 \\ T_1 &\doteq pc' = 5 \wedge x' = x \wedge y' = -y \wedge f'_0 \wedge \neg f'_1 \end{aligned}$$

2. The third funnel  $fnl_2$  performs the last step of the first iteration of the while loop. Its transition relation increases the value of  $x$  by one and, since  $y < 0$  holds in the current state,  $f_1$  is true in the next one.

$$\begin{aligned} S_2 &\doteq pc = 5 \wedge x \geq -y \wedge y < 0 \wedge f_0 \wedge \neg f_1 \\ T_2 &\doteq pc' = 3 \wedge x' = x + 1 \wedge y' = y \wedge f'_0 \wedge f'_1 \end{aligned}$$

3. The fourth funnel  $fnl_3$  represents the first step of the loop of Fig. 2 as  $fnl_0$ . However, in this case  $y$  is negative.

$$\begin{aligned} S_3 &\doteq pc = 3 \wedge x \geq -y \wedge y < 0 \wedge f_0 \wedge f_1 \\ T_3 &\doteq pc' = 4 \wedge x' = x \wedge y' = y \wedge \neg f'_0 \wedge \neg f'_1 \end{aligned}$$

4. The fifth funnel  $fnl_4$  is analogous to  $fnl_1$ , but has negative value of  $y$ .

$$\begin{aligned} S_4 &\doteq pc = 4 \wedge x \geq -y \wedge y < 0 \wedge \neg f_0 \wedge \neg f_1 \\ T_4 &\doteq pc' = 5 \wedge x' = x \wedge y' = -y \wedge \neg f'_0 \wedge f'_1 \end{aligned}$$

5. Finally, funnel  $fnl_5$  is analogous to  $fnl_2$ , but has positive value of  $y$ .

$$\begin{aligned} S_5 &\doteq pc = 5 \wedge x \geq y \wedge y > 0 \wedge \neg f_0 \wedge f_1 \\ T_5 &\doteq pc' = 3 \wedge x' = x + 1 \wedge y' = y \wedge f'_0 \wedge f'_1 \end{aligned}$$

It can be easily observed that each funnel satisfies all hypotheses of Def. 1 and the funnels are correctly chained (Def. 2) by definition of the destination regions. Notice that every region and transition of *floop* is a purely conjunctive formula and both  $S_0$  and  $S_3$  underapproximate the fair states. Therefore, in every iteration through *floop* we visit the fair states twice, in  $S_0$  with positive  $y$

and in  $S_3$  with negative  $y$ .  $floop$  satisfies all hypotheses of Th. 1 and represents at least one counterexample for our initial LTL model checking problem.

It is possible to define a funnel-loop composed of a single funnel  $fnl \doteq \langle S, T, D, RF \rangle$ , where the components can be defined in terms of the funnels we defined above as follows. The source region is the union of the source regions of the  $\{fnl_i\}_{i=0}^5$ :  $S \doteq \bigvee_{i=0}^5 S_i$ . The destination region is the last destination region of  $floop$ :  $D \doteq D_5$ . The transition relation can be defined as  $T \doteq \bigvee_{i=0}^5 (S_i \wedge T_i)$  by observing that the source regions  $\{S_i\}_{i=0}^5$  are pairwise-disjoint. Finally, the ranking function RF is defined as a function that maps every assignment to the symbols in  $V$  to a number in  $\mathbb{N}$  such that it assigns decreasing values to states in the regions  $S_0, \dots, S_4$  and assigns the constant 0 to states in  $S_5$ :

$$RF(V) \doteq \begin{cases} 0 & \text{if } S_5(V), \\ 1 & \text{if } S_4(V), \\ 2 & \text{if } S_3(V), \\ 3 & \text{if } S_2(V), \\ 4 & \text{if } S_1(V), \\ 5 & \text{otherwise.} \end{cases}$$

By construction the transition relation maps every state in  $S_0$  to some state in  $S_1$ , which is in turn mapped into  $S_2$  and so on. Therefore, every state in  $S \wedge RF > 0$  is mapped to some other state in  $S$  in which the ranking function has lower value.  $S \wedge RF = 0$  is equivalent to  $S_5$  and in such region  $T$  corresponds to  $T_5$ . Therefore, in a single transition we reach  $D_5$  that, by definition, is equivalent to  $D$  and contained in  $S_0$ .

## 6. Model decomposition via Existential Components

In the previous section we segmented the paths of a fair transition system into funnels representing finite paths. In the following we adopt an orthogonal view and decompose the system with respect to a partitioning of its symbols. For each set of symbols, an *existential component* ( $E$ -component) describes their behaviour with respect to a set of regions and represents a set of loops over such regions. Each  $E$ -component represents some infinite behaviour that a subset of the symbols can exhibit, provided that all other symbols satisfy a set of assumptions. Therefore, while funnels describe sets of finite paths,  $E$ -components describe (possibly empty) sets of infinite paths.

We will show how  $E$ -components can be obtained from funnel-loops with an additional restriction on their transition relation, hence how an  $E$ -component can be constructed by concatenating funnels.

We then compose  $E$ -components to obtain another  $E$ -component whose loops consider the union of the symbols of the smaller ones. We compose them until we obtain a component considering all the symbols of the system. Among all its loops we search for one that is also fair. We then restrict its language to only fair paths by projecting the  $E$ -component over the regions of the fair loop.

We show that such  $E$ -component corresponds to a funnel-loop for the transition system, hence proving that it admits at least one fair path.

We first define the structure and properties of the  $E$ -components and we show under which conditions a funnel-loop corresponds to an  $E$ -component. Then, we define the composition and projection operators for  $E$ -components and, finally, we show how such operators allow the representation of a funnel-loop that satisfies all hypotheses of Th. 1.

### 6.1. $E$ -component

Figure 5:  $E$ -component with two regions showing the three kinds of transitions.

An  $E$ -component is a transition system associated with a set of regions, assumptions and ranking functions. We call the conjunction of a region and its corresponding assumption *restricted region* and, in addition,  $E$ -components associate to each restricted region a ranking function. An  $E$ -component is such that its restricted regions group states with “similar behaviour” with respect to the transition relation. If some state in a restricted region allows for a transition with certain characteristics, then a transition with the same characteristics must exist for all states in the restricted region, hence the name existential components. In the following, we first describe in more detail what we mean by similar behaviour via the definition of three predicates that classify transitions. Then, we employ these predicates to formally define  $E$ -components. Finally, we characterise the language of such components.

We are interested in transitions representing self-loops over the restricted regions of two types: self-loops in which the ranking function decreases and self-loops in which the ranking function remains constant. We call them *ranked* and *stutter* transitions respectively and characterise them using two relations  $rankedT_j(V, V')$  and  $stutterT_j(V, V')$  over symbols  $V$  and  $V'$ . A transition in the restricted region with index  $j$  is a ranked transition iff  $rankedT_j$  holds and it is a stutter transition iff  $stutterT_j$  does. Finally, we consider transitions between possibly distinct restricted regions, starting from a state in which the ranking function is  $\mathbf{0}$  and reaching some state in the second region. We call them *progress* transitions and characterise them using the predicate  $progressT_{j,j'}(V, V')$ . We call a transition a progress transition from region  $j$  to region  $j'$  iff  $progressT_{j,j'}$  holds. Therefore, we distinguish three kinds of transitions between regions and require that either no state allows for a transition of a given kind or all states in the same restricted region admit such a transition.

We now proceed to formally define  $E$ -components and their operators. For a set of symbols  $V$ , let  $\mathcal{R} \doteq \{R_j(V)\}_{j=0}^{m-1}$  be the set of regions,  $\mathcal{A} \doteq \{A_j(V)\}_{j=0}^{m-1}$  be the set of assumptions and  $\mathcal{W} \doteq \{\text{RF}_j(V)\}_{j=0}^{m-1}$  be the set of ranking functions. Then,  $R_j \wedge A_j$  is the  $j^{\text{th}}$  restricted region and  $\text{RF}_j$  is the ranking function associated to it. We define the three relations that classify the transitions as follows:

$$\begin{aligned} \text{ranked}T_j(V, V') &\doteq R_j \wedge A_j \wedge \mathbf{0}_j <_j \text{RF}_j \wedge R'_j \wedge A'_j \wedge \text{RF}'_j < \text{RF}_j \\ \text{stutter}T_j(V, V') &\doteq R_j \wedge A_j \wedge R'_j \wedge A'_j \wedge \text{RF}'_j = \text{RF}_j \\ \text{progress}T_{j,j'}(V, V') &\doteq R_j \wedge A_j \wedge \mathbf{0}_j = \text{RF}_j \wedge R'_{j'} \wedge A'_{j'} \end{aligned}$$

Notice that the relations  $\text{ranked}T_j$  and  $\text{stutter}T_j$  are always disjoint; in the first case the ranking function strictly decreases, while in the second one it must remain constant. However, they are not a partitioning of all possible transitions. In fact, transitions in which the ranking function increases or that  
550 move to another region are in neither of the two sets of transitions. In addition,  $\text{progress}T_{j,j'}$  and  $\text{ranked}T_j$  are always disjoint by definition, while the first one could have a non-empty intersection with  $\text{stutter}T_j$  if  $j = j'$ . In particular, all transitions that both start and end in a state satisfying  $R_j \wedge A_j \wedge \text{RF}_j = \mathbf{0}_j$  are in the intersection of  $\text{stutter}T_j$  and  $\text{progress}T_{j,j}$ . Therefore, the existence  
555 of one such transition implies that all states in the restricted region must allow for at least one stutter transition. In addition, for the states in which  $\text{RF}_j = \mathbf{0}_j$ , this transition is also a progress transition, hence they all admit at least one progress transition that remains in the same region.

We remark that  $E$ -components represent the possibility of performing such  
560 transitions: they group states for which there exists a successor along the same transition types.

Given a partitioning  $\{V^i\}_{i=0}^n$  of the symbols  $V$  we want to define the restricted regions such that they allow a set of next assignments to the symbols in a single partition  $V^i$ , while the assignment to the symbols in  $V^{\neq i} \doteq V \setminus V^i$  is  
565 abstracted and only the assumptions are retained. For this reason, we introduce a quantifier alternation  $(\exists V^{i'} \forall V^{\neq i'})$ , and require the existence of a transition of the given type for every assignment to the  $V^{\neq i'}$  satisfying the corresponding assumptions. Therefore, we now formally define  $E$ -components as follows.

**Definition 3.** *E-component.* Given a set of symbols  $V$  such that  $\{V^i\}_{i=0}^n$  is a  
570 partitioning of  $V$  for some  $n \in \mathbb{N}$ . An  $E$ -component  $H^i$  of length  $m^i \in \mathbb{N}$  and responsible for  $V^i$  is a transition system  $\langle V, I^i(V), T^i(V, V') \rangle$  associated with:

- a set of regions  $\mathcal{R}^i \doteq \{R_j^i(V) \mid 0 \leq j < m^i\}$ ,
- a set of assumptions  $\mathcal{A}^i \doteq \{A_j^i(V^{\neq i}) \mid 0 \leq j < m^i\}$ , where  $V^{\neq i} \doteq \bigcup_{0 \leq k < n, k \neq i} V^k$  and  $A_j^i(V^{\neq i}) \doteq \bigwedge_{0 \leq k < n, k \neq i} A_j^{i,k}(V^k)$
- 575 • a set of functions  $\mathcal{W}^i \doteq \{\text{RF}_j^i(V) \mid 0 \leq j < m^i\}$  such that each  $\text{RF}_j^i$  is a ranking function with respect to a well-founded relation  $<_j^i$  and minimal element  $\mathbf{0}_j^i$ .

such that the following hold:

**I .** The set of initial states  $I^i(V)$  of  $H^i$  is a subset of the union of the restricted regions:

$$H^i \models \bigvee_{j=0}^{m^i-1} R_j^i \wedge A_j^i$$

**II .** Either no state admits a ranked transition or all states do.

$$\begin{aligned} \forall j : 0 \leq j < m^i &\rightarrow \\ \exists V, V' : \text{ranked}T_j(V, V') &\models \\ \forall V \exists V^{i'} \forall V^{\neq i'} : R_j^i \wedge A_j^i \wedge \mathbf{0}_j^{< i} \text{RF}_j^i \wedge A_j^{i'} &\rightarrow R_j^{i'} \wedge T^i \wedge \text{RF}_j^{i'} <_j^i \text{RF}_j^i \end{aligned}$$

**III .** Either no state admits a stutter transition or all states do.

$$\begin{aligned} \forall j : 0 \leq j < m^i &\rightarrow \\ \exists V, V' : \text{stutter}T_j(V, V') &\models \\ \forall V \exists V^{i'} \forall V^{\neq i'} : R_j^i \wedge A_j^i \wedge A_j^{i'} &\rightarrow R_j^{i'} \wedge T^i \wedge \text{RF}_j^{i'} = \text{RF}_j^i \end{aligned}$$

**IV .** All states admit progress transitions with the same destination regions: they reach the same restricted regions.

$$\begin{aligned} \forall j, j' : 0 \leq j < m^i \wedge 0 \leq j' < m^i &\rightarrow \\ \exists V, V' : \text{progress}T_{j, j'}(V, V') &\models \\ \forall V \exists V^{i'} \forall V^{\neq i'} : R_j^i \wedge A_j^i \wedge \text{RF}_j^i = \mathbf{0}_j^i \wedge A_{j'}^{i'} &\rightarrow R_{j'}^{i'} \wedge T^i \end{aligned}$$

When clear from the context we will simply write  $\mathbf{0}$  and  $<$  for  $\mathbf{0}_j^i$  and  $<_j^i$  respectively. In the definition, each assumption  $A_j^i(V^{\neq i})$  of  $E$ -component  $i$  at index  $j$  is composed of  $n$  conjuncts  $\{A_j^{i,k}(V^k)\}_{0 \leq k < n, k \neq i}$  where each conjunct is a formula over the symbols in a single partition  $V^k$  different from  $V^i$ .

We define the language of an  $E$ -component  $H \doteq \langle V, I, T \rangle$  over  $\mathcal{R}$ ,  $\mathcal{A}$  and  $\mathcal{W}$ , written  $\mathcal{L}(H)$ , as the language of the corresponding transition system  $M \doteq \langle V, I, T^M, \top \rangle$ , where  $T^M$  is defined as follows:

$$T^M \doteq T \wedge \left( \bigvee_{j=0}^{m-1} R_j' \wedge A_j' \right) \wedge \bigwedge_{j=0}^{m-1} (R_j \wedge A_j \wedge \mathbf{0} < \text{RF}_j) \rightarrow (R_j' \wedge A_j' \wedge \text{RF}_j' \leq \text{RF}_j)$$

Therefore, we consider only paths that remain within the set of restricted regions and move from one region to another only if the corresponding ranking function is equal to the minimal element: we can perform only ranked or stutter transitions as long as the ranking function corresponding to the current region is greater than its minimal element.

590 As for funnel-loops, also the definition of  $E$ -component allows for regions with non-empty intersection. Similarly to the previous case, this eases the construction of these structures since it has more permissive constraints. However, for every  $E$ -component there exists one with pairwise-disjoint regions that admits the same language.<sup>6</sup> For this reason, when proving statements about the language of these structures, we assume without loss of generality the regions of the  $E$ -components to be pairwise-disjoint.

### 6.2. Example decomposition

We now describe a possible decomposition of our running example (Sec. 4) into  $E$ -components. The fair transition system  $Ex$  is defined over the set of variables  $V \doteq \{x, y, pc, f_0, f_1\}$ . We consider one variable at a time and define a component representing some of its possible behaviours in the system. It is possible to define many different components for every subset of the symbols, for the sake of brevity and clarity we only describe one for each symbol. In the following  $E$ -components we implicitly define every set of initial states as the disjunction of the regions and every ranking function as always equal to its minimal element, hence the  $E$ -components will admit no ranked transition.

Consider first the program counter  $pc$ . From the transition relation of  $Ex$  it is immediately apparent that the variable will keep assuming the values  $[3, 4, 5]$  in this order. For this reason we define a  $E$ -component  $H^{pc}$ , depicted in Fig. 6.  $H^{pc}$  is responsible for  $pc$  and its three regions are defined as  $R_0^{pc} \doteq pc = 3$ ,  $R_1^{pc} \doteq pc = 4$  and  $R_2^{pc} \doteq pc = 5$ . Then, its transition relation is the disjunction of the 3 progress transitions between the regions:  $T^{pc} \doteq (pc = 3 \wedge pc' = 4) \vee (pc = 4 \wedge pc' = 5) \vee (pc = 5 \wedge pc' = 3)$ . We do not introduce any self-loop on the regions, since none exists in the transition relation of  $Ex$ . Finally, this behaviour does not require any assumption. In fact, the transition relation  $T^{pc}$  is sufficient to ensure that we move from one region to another without having to assume anything about the other symbols.

Consider now the Boolean symbols  $f_0$  and  $f_1$ . In this case, we define two  $E$ -components:  $H^{f_0}$  for  $f_0$  and  $H^{f_1}$  for  $f_1$ . The two  $E$ -components are shown in Fig. 7. In both  $E$ -components we need to distinguish the truth value of the two symbols in order to identify the fair states, hence we define each  $E$ -component using two regions. For  $i \in \{0, 1\}$ , let  $R_0^{f_i}, R_1^{f_i}$  be the regions of  $H^{f_i}$  and  $T^{f_i}$  its transition relation. We define the two regions such that one corresponds to the case in which the variable is assigned to true and the other to the case in which the variable is false. In  $Ex$

Figure 7:  $E$ -components responsible for  $f_i$ .

<sup>6</sup>See Appendix B.2 for a proof.

the two variables can remain constant for any number of steps and toggle their truth value when a certain condition is met. The simplest components we can define in this case are defined as  $R_0^{f_i} \doteq f_i$ ,  $R_1^{f_i} \doteq \neg f_i$  and  $T^{f_i} \doteq \top$ , for  $i \in \{0, 1\}$ ,  
635 with no assumptions on the other symbols.

Consider now the variable  $y$  and we define  $H^y$  as the  $E$ -component responsible for such variable. In the transition relation of  $Ex$  the variable appears in the following predicates  $\{y < 0, y > 0, x^2 \geq xy, y' = y\}$ . In only one case it appears together with another symbol:  $x^2 \geq xy$ . We can observe that if  $|x| \geq |y|$  then  
640 the predicate must hold. This suggests a dependency between  $x$  and  $y$  and for this reason we could define a single  $E$ -component that considers both symbols together. However, we would like to keep them separated for this example. We break the dependency between the two symbols by considering the stronger conditions  $x \geq 1$  and  $y \leq 1$ . Then, the presence of  $y < 0$  and  $y > 0$  suggests the need for two regions to distinguish the sign of the variable. Fig. 8 depicts  $H^y$ .

The  $E$ -component has two regions:  $R_0^y \doteq y = -1$  and  $R_1^y \doteq y = 1$ . The regions differentiate the two cases and we introduce two corresponding assumptions  $A_0^y \doteq x \geq 1$  and  $A_1^y \doteq x \geq 1$ . Finally, we define the transition relation  $T^y$  of  $H^y$  such that it allows stutter transitions in both regions and also progress transitions to move from one  
645 region to the other:  $T^y \doteq y' = y \vee y' = -y$ .

Figure 8:  $E$ -component responsible for  $y$ .

The only remaining symbol is  $x$ , for which we define the  $E$ -component  $H^x$  depicted in Fig 9. In the transition relation of  $Ex$  the variable appears in the following predicates  
660  $\{x^2 \geq xy, x' = x, x' = x + 1\}$ . We apply the same reasoning as above to analyse the predicate  $x^2 \geq xy$  and obtain a single region  $R_0^x \doteq x \geq 1$  with assumption  $A_0^x \doteq y \leq 1$  for  $H^x$ . We define the transition relation  $T^x$  of

Figure 9:  $E$ -component responsible for  $x$ .

665  $H^x$  as the disjunction of the two remaining predicates,  $T^x \doteq x' = x \vee x' = x + 1$ .

The purpose of  $E$ -components is to split the process of identifying some fair path into two phases. In the first phase, one symbol or one group of closely related symbols should be considered at a time to identify possible infinite behaviours over them, as exemplified above. The successive step requires to identify  
670 how they should be composed in order to obtain a structure that represents fair paths of the transition system. For this reason, in §6.4 we introduce two operators over  $E$ -components. The operators need to ensure that the components to be combined are compatible and preserve the existence of the infinite behaviours. We achieve this by combining  $E$ -components such that the respective assumptions are met. §6.5 shows how the  $E$ -components we defined above  
675 can be composed to prove the existence of a fair path in  $Ex$ .

### 6.3. From funnel-loops to $E$ -components

The following theorem shows the correspondence between a funnel-loop and an  $E$ -component. Therefore, it enables the use of funnels and funnel-loops in the decomposition of a system.

**Theorem 3.** *Given a set of symbols  $\hat{V} \subseteq V$ , a funnel-loop  $floop$  composed of funnels  $[fnl_i]_{i=0}^{n-1}$  such that all its transition relations are of the form  $T_i(V, \hat{V}')$  corresponds to an  $E$ -component  $H \doteq \langle V, \bigvee_{i=0}^{n-1} S_i, \bigvee_{i=0}^{n-1} S_i \wedge T_i \rangle$  responsible for symbols  $\hat{V}$  and associated with regions  $\{S_i\}_{i=0}^{n-1}$ , ranking functions  $\{RF_i\}_{i=0}^{n-1}$  and assumptions  $\{\top\}_{i=0}^{n-1}$ .*

*Proof.* We show that  $H$  satisfies all hypotheses of Def. 3.

- I** By definition all assumptions are  $\top$  and the initial states are defined as the union of the regions. Therefore, Hyp. **I** holds.
- II** Hyp. **F.1** ensures that in every region  $S_i$ ,  $T_i$  always allows for a successor state. Therefore, also  $\bigvee_{i=0}^{n-1} S_i \wedge T_i$  is left-total in the union of the regions. Hyp. **F.3** ensures that every self-loop on  $S_i$  decreases the associated ranking function  $RF_i$ . If a self-loop exist such transition is a ranked transition and all such transitions are ranked. All such states admit a successor and the successor must decrease the value of the ranking function. Therefore, Hyp. **II** holds.
- III** As observed in the previous case, all self-loops on a region must decrease the corresponding transition relation. Therefore,  $H$  admits no stutter transitions and Hyp. **III** holds.
- IV** Hyp. **F.4** ensures that from every region  $S_i$  when the ranking function  $RF_i$  is equal to  $\mathbf{0}$ , in one transition  $T_i$  we always reach a state in  $D_i$  and, by hypotheses **FL.1** and **FL.2**, such state is in the following region  $S_{(i+1)\%n}$ . Since, the transition relation is left-total by Hyp. **F.1**, then all states in  $S_i \wedge RF_i = \mathbf{0}$  admit at least one and only successors in  $S_{(i+1)\%n}$ . Therefore, Hyp. **IV** holds.

□

### 6.4. Operators over $E$ -component

We now define the projection and composition operators for  $E$ -components. Intuitively, the first operator shrinks an  $E$ -component by considering only a subset of its regions, while the second operator computes the product of  $n$   $E$ -components. These two operators will be useful to identify an  $E$ -component that meets some additional requirements in order to represent a funnel-loop.

*E-component projection.* We define a projection operation for  $E$ -components that can be used to obtain a smaller  $E$ -component describing a subset of the paths of the original structure. We project an  $E$ -component over an ordered  
715 subset of its regions, then we restrict the transition relation by removing all stuttering transitions and such that the progress transitions must follow the ordering of the regions and from the last region they can only reach the first one. Therefore, the projection restricts the language of an  $E$ -component to the paths that visit only regions in the sequence in order and are either finite or  
720 reach the last region infinitely often.

**Definition 4.** Given an  $E$ -component  $H \doteq \langle V, I, T \rangle$  over  $m$  regions  $\mathcal{R}$ , assumptions  $\mathcal{A}$  and ranking functions  $\mathcal{W}$ , we define its projection to a sequence of  $k$  indexes  $idxs \doteq \langle j_0^\downarrow, \dots, j_{k-1}^\downarrow \rangle$  such that  $idxs \subseteq \{0, \dots, m-1\}$  as the  $E$ -component  $H^\downarrow \doteq \langle V, I^\downarrow, T^\downarrow \rangle$  associated with regions  $\mathcal{R}^\downarrow$ , assumptions  $\mathcal{A}^\downarrow$  and ranking functions  $\mathcal{W}^\downarrow$  defined as follows:  
725

- $I^\downarrow \doteq I \wedge \bigvee_{j \in idxs} (R_j \wedge A_j)$ ;
  - $T^\downarrow \doteq T \wedge \bigwedge_{h=0}^{k-1} R_{j_h}^\downarrow \rightarrow ((R_{j_h}^{\prime\downarrow} \wedge \text{RF}_{j_h}^{\prime\downarrow} < \text{RF}_{j_h}^\downarrow) \vee (\text{RF}_{j_h}^\downarrow = \mathbf{0} \wedge R_{j_{(h+1)\%k}^\downarrow}^{\prime\downarrow}))$
  - $\mathcal{R}^\downarrow \doteq \{R_j \mid j \in idxs \wedge R_j \in \mathcal{R}\}$ ;
  - $\mathcal{A}^\downarrow \doteq \{A_j \mid j \in idxs \wedge A_j \in \mathcal{A}\}$ ;
  - $\mathcal{W}^\downarrow \doteq \{\text{RF}_j \mid j \in idxs \wedge \text{RF}_j \in \mathcal{W}\}$ .
- 730

Notice that in the projection we restrict the set of initial states to only those in one of the restricted regions corresponding to the indexes  $idxs$ , and the transition relation is strengthened such that it imposes that the regions in  $idxs$  are always visited in order. In addition, the projection operator does not  
735 modify the regions, assumptions and ranking function of an  $E$ -component, but considers a subset of them.

**Theorem 4.** The projection  $H^\downarrow$  over indexes  $idxs$  of an  $E$ -component  $H$  over regions  $\mathcal{R}$ , assumptions  $\mathcal{A}$  and ranking functions  $\mathcal{W}$  is an  $E$ -component.

The proof of Th. 4 is reported in [Appendix B.3](#).

*E-component composition.* We compose  $E$ -components such that they meet  
740 their respective assumptions. Given a set  $\{H^i\}_{i=0}^n$  of  $E$ -components, we say that a set of transitions from regions  $\{R_{j_i}^i\}_{i=0}^n$  to regions  $\{R_{j'_i}^i\}_{i=0}^n$  are *compatible*, if every transition  $T^i$  ensures that  $\bigwedge_{s=0, s \neq i}^n A_{j'_s}^{s,i}$  holds. In addition, we compose restricted regions of  $E$ -components iff the corresponding ranking functions are independent: it is possible to decrease one independently from the  
745 others. In the following we define two binary predicates *compatible* $_{\{H^i\}_{i=0}^n}$  and *indepRank* $_{\{H^i\}_{i=0}^n}$  that hold iff the two conditions are met.

transitions decreasing only that function.

$$\begin{aligned}
& \text{indepRank}_{\{H^i\}_{i=0}^n}(\hat{V}, \hat{V}') \doteq \bigwedge_{\substack{0 \leq j_0 < m^0, \dots, 0 \leq j_n < m^n \\ \text{all possible indexes for the } E\text{-components } \{H^i\}_{i=0}^n}} \\
& \left( \underbrace{\left( \sum_{i=0}^n \text{RF}_{j_i}^i(\hat{V}') < \sum_{i=0}^n \text{RF}_{j_i}^i(\hat{V}) \right)}_{\text{some ranking function decreases, all others remain constant}} \right) \wedge \\
& \underbrace{\bigwedge_{i=0}^n R_{j_i}^i(\hat{V}) \wedge A_{j_i}^i(\hat{V}^{\neq i}) \wedge R_{j_i}^i(\hat{V}') \wedge A_{j_i}^i(\hat{V}'^{\neq i'})}_{\hat{V}, \hat{V}' \text{ are in restricted regions } j_i, j'_i} \rightarrow \\
& \underbrace{\bigwedge_{i=0}^n (\forall V : (\bigwedge_{h=0}^n R_{j_h}^h(V) \wedge A_{j_h}^h(V^{\neq h})) \rightarrow \text{RF}_{j_i}^i(V) = \mathbf{0})}_{\text{current ranking function } \text{RF}_{j_i}^i \text{ is always } \mathbf{0}} \vee \\
& \underbrace{\exists V, V' : (\bigwedge_{h=0}^n R_{j_h}^h(V) \wedge A_{j_h}^h(V^{\neq h}) \wedge T^h(V, V') \wedge R_{j_h}^h(V') \wedge A_{j_h}^h(V'^{\neq h'}))}_{V, V' \text{ in same restricted regions of } \hat{V}, \hat{V}'} \wedge \\
& \underbrace{\text{RF}_{j_i}^i(V') < \text{RF}_{j_i}^i(V) \wedge (\bigwedge_{h=0, h \neq i}^n \text{RF}_{j_h}^h(V') = \text{RF}_{j_h}^h(V))}_{\text{current ranking function decreases, all others remain constant}} \wedge \\
& \text{compatible}_{\{H^k\}_{k=0}^n}(V, V')
\end{aligned}$$

755 The composition operator for a set of  $E$ -components  $\{H^i\}_{i=0}^n$  requires the corresponding sets  $\{V^i\}_{i=0}^n$  to be pairwise disjoint. We write  $\{V^i\}_{i \notin \{0, \dots, n\}}$  for the possibly empty list of other sets to complete the partitioning:  $\{V^i\}_{i=0}^n \cup \{V^i\}_{i \notin \{0, \dots, n\}}$  is a partitioning of  $V$ .

760 **Definition 7 (composition of  $E$ -components).** We define the composition of a set of  $E$ -components  $\{H^i\}_{i=0}^n$ , such that the sets of local symbols  $\{V^i\}_{i=0}^n$  are pairwise disjoint, as  $H^c \doteq \bigotimes_{i=0}^n H^i = \langle V, I^c, T^c \rangle$  where:

- $V^c \doteq \bigcup_{i=0}^n V^i$ .
- The set of regions is the intersection of the regions and assumptions over  $V^c$  of the  $E$ -components.

$$\begin{aligned}
\mathcal{R}^c \doteq & \left\{ \bigwedge_{i=0}^n R_{j_i}^i \wedge \bigwedge_{h=0, h \neq i}^n A_{j_i}^{i,h} \mid \forall i \in \{0, \dots, n\}, j_i \in \{0, \dots, m^i - 1\} : R_{j_i}^i \in \mathcal{R}^i \wedge \right. \\
& \left. \forall h \in \{0, \dots, n\} \setminus \{i\} : A_{j_i}^i \in \mathcal{A}^i \wedge A_{j_i}^{i,h} \in \mathcal{A}_{j_i}^i \right\}
\end{aligned}$$

- The set of assumptions is given by the conjunction of the assumptions of the  $\{H^i\}_{i=0}^n$  over the symbols not in  $V^c$ .

$$\mathcal{A}^c \doteq \left\{ \bigwedge_{i=0}^n \bigwedge_{h \notin \{0, \dots, n\}} A_{j_i}^{i,h} \mid \forall i \in \{0, \dots, n\}, h \notin \{0, \dots, n\}, j_i \in \{0, \dots, m^i - 1\} : \right. \\ \left. A_{j_i}^i \in \mathcal{A}^i \wedge A_{j_i}^{i,h} \in A_{j_i}^i \right\}$$

- The ranking functions for the regions are obtained by considering the sum of the ones corresponding to the regions of the  $\{H^i\}_{i=0}^n$ .

$$\mathcal{W}^c \doteq \left\{ \sum_{i=0}^n \text{RF}_{j_i}^i \mid \forall i \in \{0, \dots, n\}, j_i \in \{0, \dots, m^i - 1\} : \text{RF}_{j_i}^i \in \mathcal{W}^i \right\}$$

- $I^c \doteq \bigwedge_{i=0}^n I^i$ ;
- The set of transitions is given by the conjunction of the transition relations of the  $\{H^i\}_{i=0}^n$  restricted to the compatible transitions.

$$T^c \doteq \text{compatible}_{\{H^i\}_{i=0}^n} \wedge \text{indepRank}_{\{H^i\}_{i=0}^n} \wedge \bigwedge_{i=0}^n T^i$$

765 **Theorem 5.** Given a set of  $E$ -components  $\{H^i\}_{i=0}^n$ , their composition  $H^c \doteq \bigotimes_{i=0}^n H^i = \langle V, I^c, T^c \rangle$  is an  $E$ -component with respect to regions  $\mathcal{R}^c$ , assumptions  $\mathcal{A}^c$  and ranking functions  $\mathcal{W}^c$ .

The proof of Th. 5 is reported in [Appendix B.4](#).

770 We remark that the definition of the composition operator ensures that  $H^c$  admits only transitions that satisfy both *compatible* and *indepRank*. In addition, we consider only simple interactions between the ranking functions of different  $E$ -components. It is possible to extend the operator to allow for more complex combinations such as nesting of ranking functions or allowing the ranking function of an  $E$ -component to decrease once every time all the other  $E$ -components  
775 perform a loop over their regions. However, including this kind of compositions would make the definitions and proofs much more complex and with many more cases to be considered.

### 6.5. Example $E$ -components composition

780 We now show how the  $E$ -components we defined in Subsec. 6.2 can be combined to conclude the existence of a fair path in the fair transition system  $Ex$  defined in Sec. 4.

We first compute a  $E$ -component  $H^{f_0, f_1}$  as  $H^{f_0} \otimes H^{f_1}$ .  $H^{f_0}$  and  $H^{f_1}$  have no assumptions and all ranking functions are always equal to their minimal element. Therefore, all transitions are compatible and the result  
785 of the composition is the synchronous product of the two  $E$ -components.

Fig. 10 depicts the resulting  $E$ -component  $H^{f_0, f_1}$ .  $H^{f_0, f_1}$  has four regions, one for each of the possible truth assignments of the two Boolean symbols  $f_0$  and  $f_1$  and it allows all 16 possible transitions and self-loops over them.

We now compute  $H^{x, y}$  responsible for  $x$  and  $y$  as the composition of  $H^x$  and  $H^y$ ; the  $E$ -component is depicted in Fig. 11. The assumption of  $H^x$  re-

Figure 10:  $E$ -component responsible for  $\{f_0, f_1\}$ .

Figure 11:  $E$ -component responsible for  $\{x, y\}$ .

quires  $y \leq 1$  and both assumptions of  $H^y$  require  $x \geq 1$ . Therefore, it can be easily seen that  $H^x$  will always meet the assumptions required by  $H^y$  and vice-versa also  $H^y$  meets the assumption of  $H^x$ . Since the two  $E$ -components do not have any assumptions on the other symbols, the resulting  $E$ -component  $H^{x, y}$  has no assumptions.  $H^{x, y}$  has two regions, obtained by the conjunction of the two regions of  $H^y$  with the only region of  $H^x$ . The transition relation of  $H^{x, y}$  is given by the conjunction of the transition relations of  $H^x$  and  $H^y$ . Both regions of the  $E$ -component admit stutter transitions of two kinds: one in which both variables  $x$  and  $y$  remain constant, and one in which  $y$  is constant and  $x$  increases by one. Notice that the ranking functions of the regions are always constant and equal to the minimal element. Therefore, the transitions satisfy *indepRank* because its definition (Def. 6) is an implication in which the left-hand-side requires at least one ranking function to decrease. Finally,  $H^{x, y}$  also admits progress transitions from one region to the other of two kinds: in both cases the value of  $y$  changes its sign, while in one case  $x$  remains constant and in the other it increments by one.

Finally, we compute  $H \doteq H^{pc} \otimes H^{x, y} \otimes H^{f_0, f_1}$ . None of the  $E$ -components has assumptions and all their ranking functions are always equal to the minimal element. For this reason, all transitions are compatible and have independent ranks. Therefore, the transition relation of  $H$  is the conjunction of the transition relations of the 3  $E$ -components.  $H$  has 24 regions, given by the product of the 3 regions of  $H^{pc}$ , 2 of  $H^{x, y}$  and 4 of  $H_{f_0, f_1}$ . The regions represent all the different

configurations that can be reached by employing compatible transitions of our  $E$ -components  $H^{pc}$ ,  $H^{f_0}$ ,  $H^{f_1}$ ,  $H^x$  and  $H^y$ . Recall that our objective is to identify fair paths for the fair transition system  $Ex$  defined in Sec. 4. Not all transitions of  $H$  are also transition of  $Ex$ . For example,  $H$  admits a transition that increases the value of  $x$  from states where  $pc = 3$ , while this is not possible in  $Ex$ . However, using the projection operator we can restrict  $H$  by considering a subset of its regions. In particular, we are interested in the sequence of regions that would allow us to obtain a representation of at least one fair path for  $Ex$ . We select 6 regions and depict the projection of  $H$  over such regions in Fig. 12. We call this projection  $H^\downarrow$ . In particular we consider the following regions:

$$\begin{aligned}
R_0 &\doteq f_0 \wedge f_1 \wedge y = 1 \wedge x \geq 1 \wedge pc = 3, \\
R_1 &\doteq \neg f_0 \wedge \neg f_1 \wedge y = 1 \wedge x \geq 1 \wedge pc = 4, \\
R_2 &\doteq f_0 \wedge \neg f_1 \wedge y = -1 \wedge x \geq 1 \wedge pc = 5, \\
R_3 &\doteq f_0 \wedge f_1 \wedge y = -1 \wedge x \geq 1 \wedge pc = 3, \\
R_4 &\doteq \neg f_0 \wedge \neg f_1 \wedge y = -1 \wedge x \geq 1 \wedge pc = 4, \\
R_5 &\doteq \neg f_0 \wedge f_1 \wedge y = 1 \wedge x \geq 1 \wedge pc = 5.
\end{aligned}$$

Notice that the 6 regions underapproximate those that we have already considered in the funnel-loop described in §5.3. In particular, for every  $i \in \{0, \dots, 5\}$   $R_i$  underapproximates  $S_i$ . In fact, there is correspondence between the paths of  $H^\downarrow$  and those of the funnel-loop. Therefore,  $H^\downarrow$  proves the existence of a fair path in the language of the fair transition system  $Ex$  and we reached our goal. In the following we formalise this relationship between  $E$ -components and funnel-loops. Th. 6 details the conditions under which an  $E$ -component implies the existence of a funnel-loop proving the non-emptiness of the language of a

Figure 12:  $E$ -component responsible for all symbols.

fair transition system.

### 6.6. From $E$ -components to funnel-loops

We now provide a sequence of sufficient conditions for an  $E$ -component  $H \doteq \langle V, I, T \rangle$  over regions  $\mathcal{R}$ , assumptions  $\mathcal{A}$  and ranking functions  $\mathcal{W}$  to describe a funnel-loop.

**Theorem 6.** *Let  $M$  be a given fair transition system  $M \doteq \langle V, I^M, T^M, F^M \rangle$ . The existence of an  $E$ -component  $H \doteq \langle V, I, T \rangle$  responsible for all symbols  $V$  over regions  $\mathcal{R}$  and ranking functions  $\mathcal{W}$  of length  $m$  satisfying all the following conditions, implies the existence of a funnel-loop for  $M$ , hence the existence of at least one fair path in  $M$ .*

**H.0** *An initial state of  $H$  is reachable in  $M$ :*

$$M \rightsquigarrow I$$

**H.1** *The transition relation of  $H$ , restricted to the transitions that follow the sequence of regions  $\mathcal{R}$ , underapproximates the transition relation of  $M$ :*

$$\forall j, V, V' : R_j \wedge T \wedge ((\text{RF}'_j < \text{RF} \wedge R'_j) \vee (\text{RF}_j = \mathbf{0} \wedge R'_{(j+1)\%m})) \rightarrow T^M$$

**H.2** *From the last region in  $\mathcal{R}$ ,  $H$  can only reach fair states.*

$$\forall V, V' : R_{m-1} \wedge \text{RF}_{m-1} = \mathbf{0} \wedge T \wedge R'_0 \rightarrow F^{M'}$$

**H.3** *There must exist a transition from each  $R_j$  with  $\text{RF}_j = \mathbf{0}$  to the following region  $R_{(j+1)\%m}$ :*

$$\forall j \exists V, V' : 0 \leq j < n - 1 \rightarrow R_j \wedge \text{RF}_j = \mathbf{0} \wedge T \wedge R'_{(j+1)\%m}$$

**H.4** *If a region has a non-trivial ranking function, then it must be possible to decrease it:*

$$\forall j : 0 \leq j < m \rightarrow (\forall V : \text{RF}_j = \mathbf{0}) \vee (\exists V, V' : R_j \wedge T \wedge R'_j \wedge \text{RF}'_j < \text{RF})$$

*Proof.* Since  $H$  is responsible for all symbols  $V$ , then all assumptions in  $\mathcal{A}$  are empty. We first define the funnel-loop *floop* corresponding to the  $E$ -component  $H$  and then prove that: all of its funnels meet the hypotheses of Def. 1, *floop* is indeed a funnel-loop (Def. 2) and *floop* meets all the hypotheses of Th. 1.

Define *floop* as the concatenation of the funnels  $\{fnl_j\}_{j=0}^{m-1}$ . Each funnel  $fnl_j$  is the 4-tuple  $\langle S_j, T_j, D_j, \text{RF}_j \rangle$  such that:

- $S_j \doteq R_j$  for  $R_j \in \mathcal{R}$ ;
- $T_j \doteq T \wedge ((\text{RF}'_j < \text{RF}_j \wedge R'_j) \vee (\text{RF}_j = \mathbf{0} \wedge R'_{(j+1)\%m}))$ ;
- $D_j \doteq \exists V' : R_j \wedge \text{RF}_j = \mathbf{0} \wedge T \wedge R'_{(j+1)\%m}$ ;

- $\text{RF}_j \in \mathcal{W}$ .

We show that each  $fnl_j$  is a funnel (Def. 1).

850 **F.1**  $T_j$  is left-total with respect to  $S_j$  because  $T$  always allows for at least one successor that is either in the same region with decreasing ranking function or in the following region.  $H$  is an  $E$ -component, hence it satisfies Hyp. **II** and Hyp. **IV**. Hypotheses **H.4** and **H.3** ensure that at least one transition of both kinds exists in  $H$ . Therefore, from every state in  $S_j$  with  $\mathbf{0} < \text{RF}_j$   
855 there exists a successor in the same region with  $\text{RF}'_j < \text{RF}_j$  and from every state in  $S_j$  with  $\text{RF}_j = \mathbf{0}$ ,  $T$  admits a successor in  $S_{(j+1)\%m}$ .

**F.2** holds by construction of  $T_j$ ;  $\mathbf{0} < \text{RF}_j$  implies that the second component of the disjunction in  $T_j$  is false and  $T_j$  becomes equivalent to  $T \wedge \text{RF}'_j < \text{RF}_j \wedge R'_j$  which implies  $R'_j$ .

860 **F.3** holds by construction of  $T_j$ ;  $\mathbf{0} < \text{RF}_j$  implies that the second component of the disjunction in  $T_j$  is false and  $T_j$  becomes equivalent to  $T \wedge \text{RF}'_j < \text{RF}_j \wedge R'_j$  which implies  $\text{RF}'_j < \text{RF}_j$ .

**F.4** holds by construction of  $D_j$ : we defined it as the existential image of  $R_j \wedge \text{RF}_j = \mathbf{0}$  with respect to  $T \wedge R'_{(j+1)\%m}$ .

865 We now show that  $floop$  is a funnel-loop (Def. 2).

**FL.1**, **FL.2** By construction each  $T_j$ , from a state in  $R_j \wedge \text{RF}_j = \mathbf{0}$  with  $j < m$  can only reach states that are in  $R_{(j+1)\%m}$ . Therefore, by construction of  $D_j$  both Hyp. **FL.1** (for  $j < m - 1$  and Hyp. **FL.2** (for  $j = m - 1$ ) hold.

Finally, we show that  $floop$  meets all hypotheses of Th. 1.

870 **FF.1** Hyp. **I** ensures that the initial states of  $H$  underapproximate the union of its regions. Hyp. **H.0** ensures that there exist a reachable initial state in  $H$ . Therefore, there is a reachable state in the union of the regions and Hyp. **FF.1** holds.

**FF.2**  $D_{m-1}$  is defined as the existential image of  $R_{m-1} \wedge \text{RF}_{m-1} = \mathbf{0}$  with respect to  $T \wedge R'_0$ . Hyp. **H.2** ensures that all such states are also fair, hence Hyp. **FF.2** holds.

**FF.3** By construction each  $S_j \wedge T_j$  underapproximates  $T$ . Hyp. **H.1** ensures that  $T$  underapproximates  $T^M$ . Therefore each  $S_j \wedge T_j$  underapproximates  $T^M$ .

□

## 880 7. Search procedure

This section describes the procedure for the synthesis of a funnel-loop. Given a fair transition system  $M$  and a set of  $E$ -components  $\mathcal{H}$ , the procedure tries to find, in a fully automated manner, a funnel-loop  $fnl\_loop$  for  $M$  and a finite path

of  $M$  ending in a region of  $fnl\_loop$ .  $\mathcal{H}$  is a possibly empty set of  $E$ -components  
885 provided by the user to guide the search. For this reason we will refer to them  
as *hints*. The procedure selects a possibly empty subset of hints and uses them  
as building blocks to define the funnel-loop while synthesising the missing compo-  
nents. When the set of hints is empty the procedure identifies a funnel-loop  
for a fair transition system without relying on any additional information. In  
890 the following, we call trivial hint the  $E$ -component  $H \doteq \langle V, \top, \top \rangle$  responsible for  
no symbols ( $V^H \doteq \emptyset$ ) such that all its regions and assumptions are the constant  
 $\top$  and all its ranking functions are always  $\mathbf{0}$ .

---

Alg. 1 describes the main steps of the procedure. We reduce the synthesis  
problem to a sequence of SMT queries. In order to reduce the search space,  
895 given a  $E$ -component  $H$  we only look for funnel-loops obtained by deterministic  
completions of  $H$ ; we strengthen the transition relation of  $H$  by adding deter-  
ministic assignments to the symbols for which  $H$  is not responsible. More in  
detail, Alg. 1 enumerates candidate conjunctive fair loops of the fair transition  
system and compositions of  $E$ -components that admit such loop (line 1). If  
900 GENERATE-CANDIDATE-LOOPS selects no hints or  $\mathcal{H}$  is empty the returned  $H$  is  
the trivial hint. For each candidate loop, the procedure generates a sequence  
of parameterised funnel-loops, called funnel-loop templates, as a strengthening  
of the corresponding  $E$ -component (line 3). The predicates of a funnel-loop  
template are over the symbols of the system  $M$  and a set of parameters  $P$ . The  
905 procedure searches an assignment to the parameters such that all the hypothe-  
ses of Defs. 1 and 2 and of Th. 1 hold. At line 4 the procedure obtains the  
 $\exists\forall$ -quantified problem associated with the funnel-loop template and then, at  
line 5 tries to solve it. Finally, at line 7, it replaces the parameters with the  
assignment identified at the previous step, thus obtaining the desired funnel-loop.

910 The procedure relies on ranking functions to perform two different tasks.  
Alg. 2 tries to synthesise ranking functions to avoid considering candidate loops

for which we know a ranking function exists. The existence of the ranking function proves that the loop must eventually terminate, hence it cannot correspond to an infinite path. Then, ranking function templates are also used as  
915 components for the funnels of the funnel-loop template generated by Alg. 3.

Before going into the details of the procedure, we first show its application to our running example. We then describe how we represent and enumerate candidate loops and compositions of  $E$ -components for the transition system  $M$ . After that, we detail how a funnel-loop template is generated from a candidate  
920 loop and  $E$ -component. Finally, we report the synthesis problem associated with a funnel-loop template.

### 7.1. Example funnel-loop search

We first recall the definition of the fair transition system  $Ex$  we introduced in Sec. 4. Let  $V \doteq \{x, y, pc, f_0, f_1\}$  be a set of symbols such that  $pc$  and  $x$  are integer variables,  $y$  has real type and  $f_0$  and  $f_1$  are two Boolean symbols. Then, the fair transition system is  $Ex \doteq \langle V, I, T, F \rangle$ , where:

$$\begin{aligned}
I &\doteq pc = 3; \\
F &\doteq f_0 \wedge f_1; \\
T &\doteq (pc = 3 \rightarrow (x^2 \geq xy \wedge pc' = 4 \wedge x' = x \wedge y' = y)) \wedge \\
&\quad (pc = 4 \rightarrow (pc' = 5 \wedge x' = x)) \wedge \\
&\quad (pc = 5 \rightarrow (pc' = 3 \wedge x' = x + 1 \wedge y' = y)) \wedge \\
&\quad ((f_0 \wedge f_1) \rightarrow (\neg f'_0 \wedge \neg f'_1)) \wedge \\
&\quad (f'_0 \rightarrow (f_0 \vee y > 0)) \wedge (f'_1 \rightarrow (f_1 \vee y < 0)).
\end{aligned}$$

In addition, we assume no hints were provided, i.e.  $\mathcal{H} \doteq \emptyset$ . Let  $Ex$  and  $\mathcal{H}$  be the inputs of our procedure. Alg. 1 at line 1 iterates over the candidate loops generated from  $Ex$  and  $\mathcal{H}$ .  $\langle \mathbf{v}_0, loop\_r, loop\_t, H \rangle$ .  $loop\_r$  and  $loop\_t$  are sequences of predicates over  $V$  and  $V \cup V'$  respectively. The two sequences, together with  $H$ , describe the abstract loop. Instead,  $\mathbf{v}_0$  is a state in the first region of  $loop\_r$  reachable in  $Ex$ . Therefore, it is the last state of a finite path  $prefix$  of  $Ex$  that starts its initial states and ends in  $\mathbf{v}_0$ . We compute  $\langle \mathbf{v}_0, loop\_r, loop\_t, H \rangle$  by employing a liveness-to-safety [8] transformation of  $Ex$  where the loop-back is identified in an abstract state. We then employ an unrolling of the transition relation in the style of Bounded Model Checking (BMC) [15] to enumerate concrete paths of  $Ex$  with such abstract loop-back. The stem of this concrete path corresponds to our  $prefix$ .  $loop\_r$  and  $loop\_t$  are obtained from the loop of the concrete path by computing an implicant for the unrolling of the transition relation of  $Ex$ . We then partition the predicates in the implicant depending on their index in the unrolling and whether they contain only current ( $loop\_r$ ) or both current and next-state variables ( $loop\_t$ ). Assume we are considering a BMC unrolling of 6 transitions of  $Ex$  and obtain

the following path:

$$\begin{aligned}
0: & f_0 \wedge f_1 \wedge pc = 3 \wedge x = 1 \wedge y = 1; \\
1: & \neg f_0 \wedge \neg f_1 \wedge pc = 4 \wedge x = 1 \wedge y = 1; \\
2: & f_0 \wedge \neg f_1 \wedge pc = 5 \wedge x = 1 \wedge y = -1; \\
3: & f_0 \wedge f_1 \wedge pc = 3 \wedge x = 2 \wedge y = -1; \\
4: & \neg f_0 \wedge \neg f_1 \wedge pc = 4 \wedge x = 2 \wedge y = -1; \\
5: & \neg f_0 \wedge f_1 \wedge pc = 5 \wedge x = 2 \wedge y = 2; \\
6: & f_0 \wedge f_1 \wedge pc = 3 \wedge x = 3 \wedge y = 2;
\end{aligned}$$

where the states with indexes 0 and 6 correspond to the same state in the abstract space defined by the predicates appearing in  $Ex$ . We use this path to compute an implicant for the formula  $F(V_0) \wedge \bigwedge_{i=0}^5 T(V_i, V_{i+1})$ . The implicant is a conjunction of a subset of the atoms appearing in the formula such that it implies the formula itself. In addition, the path is a satisfying assignment also for the implicant. Each predicate in the unrolling depends either on a single  $V_i$  or on  $V_i \cup V_{i+1}$  for some  $i$ , hence the same holds for the predicates in the implicant. We partition the atoms of the implicant such that the predicates that depend only on  $V_i$  are in  $loop\_r[i\%6]$  and those that depend on  $V_i \cup V_{i+1}$  are placed in  $loop\_t[i]$ . The first and last state correspond to the same abstract region, hence their predicates are placed together into  $loop\_r[0]$ .

The computation above allows us to obtain the following. Since  $\mathcal{H}$  is empty  $H$  is the trivial hint. The *prefix* contains a single state:  $prefix \doteq [f_0 \wedge f_1 \wedge pc = 3 \wedge x = 1 \wedge y = 1]$ ,  $loop\_r$  and  $loop\_t$  have length 6 and each  $loop\_r[i] \wedge loop\_t[i]$  underapproximates the transition relation  $T$ .

$$\begin{array}{ll}
loop\_r \doteq [ & loop\_t \doteq [ \\
0: & f_0 \wedge f_1 \wedge pc = 3 \wedge x^2 \geq xy, & \neg f'_0 \wedge \neg f'_1 \wedge pc' = 4 \wedge x' = x \wedge y' = y, \\
1: & \neg f_0 \wedge \neg f_1 \wedge pc = 4 \wedge y > 0, & f'_0 \wedge \neg f'_1 \wedge pc' = 5 \wedge x' = x, \\
2: & f_0 \wedge \neg f_1 \wedge pc = 5 \wedge y < 0, & f'_0 \wedge f'_1 \wedge pc' = 3 \wedge x' = x + 1 \wedge y' = y, \\
3: & f_0 \wedge f_1 \wedge pc = 3 \wedge x^2 \geq xy, & \neg f'_0 \wedge \neg f'_1 \wedge pc' = 4 \wedge x' = x \wedge y' = y, \\
4: & \neg f_0 \wedge \neg f_1 \wedge pc = 4 \wedge y < 0, & \neg f'_0 \wedge f'_1 \wedge pc' = 5 \wedge x' = x, \\
5: & \neg f_0 \wedge f_1 \wedge pc = 5 \wedge y > 0] & f'_0 \wedge f'_1 \wedge pc' = 3 \wedge x' = x + 1 \wedge y' = y]
\end{array}$$

We now search for a funnel-loop as a strengthening of this candidate loop. Notice that the candidate loop by itself is not sufficient. In fact,  $loop\_t[1]$  does not constrain the next assignment of  $y'$ , hence it does not guarantee that  $y < 0$  holds in the next state as required by  $loop\_r[2]$ . Before building the funnel-loop template, we can perform some simplifications on the candidate loop to reduce the number of parameters introduced by the template and ease the presentation. First of all, notice that every step  $i$  in  $loop\_t$  assigns to the variables  $f_0$ ,  $f_1$  and  $pc$  a constant value that corresponds to the one required by  $loop\_r[(i+1)\%6]$ . Therefore, for brevity, we will omit such constraints from the formulae in  $loop\_t$  and focus our presentation on  $x$  and  $y$ . Moreover, many steps in  $loop\_t$  require

$x$  or  $y$  to remain constant. Consider a step  $t \doteq \text{loop\_t}[i]$  that requires  $y$  to be constant. We need  $t$  to map states in  $r_s \doteq \text{loop\_r}[i]$  into  $r_d \doteq \text{loop\_r}[(i+1)\%6]$ . Therefore, if  $r_d$  requires  $y$  to be positive ( $y > 0$ ), then the same must hold in  $r_s$  and vice-versa. We can exploit identity relations in  $\text{loop\_t}$  to symbolically propagate constraints in  $\text{loop\_r}$ . By employing these transformations we obtain the following:

$$\begin{array}{ll}
\text{loop\_r} \doteq [ & \text{loop\_t} \doteq [ \\
0 : & f_0 \wedge f_1 \wedge pc = 3 \wedge x^2 \geq xy \wedge y > 0, & x' = x \wedge y' = y, \\
1 : & \neg f_0 \wedge \neg f_1 \wedge pc = 4 \wedge y > 0, & x' = x, \\
2 : & f_0 \wedge \neg f_1 \wedge pc = 5 \wedge y < 0, & x' = x + 1 \wedge y' = y, \\
3 : & f_0 \wedge f_1 \wedge pc = 3 \wedge x^2 \geq xy \wedge y < 0, & x' = x \wedge y' = y, \\
4 : & \neg f_0 \wedge \neg f_1 \wedge pc = 4 \wedge y < 0, & x' = x, \\
5 : & \neg f_0 \wedge f_1 \wedge pc = 5 \wedge y > 0] & x' = x + 1 \wedge y' = y]
\end{array}$$

We now define a funnel-loop template of length 6 that can be generated by the procedure at line 3. For  $i \in \{0, \dots, 5\}$ , we define the  $i^{\text{th}}$  funnel of the template as a strengthening of  $\text{loop\_r}[i]$  and  $\text{loop\_t}[i]$ . In the template we use symbols from the set  $P \doteq \{p_i | i \in \mathbb{N}\}$ , disjoint from  $V$ , as parameters. The parameters are variables for which we need to find an assignment such that the template corresponds to an actual funnel-loop. Notice that the steps in  $\text{loop\_t}$  already prescribe functional assignments for all variables but for  $y$  at steps 1 and 4. For this reason, we introduce 2 parametric affine expressions to underapproximate the assignment to  $y'$ . In addition, we introduce parametric affine inequalities over  $x$  and  $y$  to strengthen the elements of  $\text{loop\_r}$ . Also in this case we reduce the number of parameters we need to introduce by exploiting the functional assignments of  $\text{loop\_t}$ . For  $i \in \{0, 1, \dots, 5\}$ , let  $\text{fnl}_i \doteq \langle \text{src}_i, t_i, \mathbf{0}, \text{dst}_i \rangle$  be the  $i^{\text{th}}$  funnel of the template. We define each destination region  $\text{dst}_i$  as the set of states reachable from the previous source region when the ranking function is equal to the minimal element. Since we defined every ranking function to be always equal to the minimal element, we define each destination region as:

$$\text{dst}_i \doteq \exists V : \text{src}_i(V, P) \wedge t_i(V, V', P).$$

We define the source regions and transition relations as follows.

$$\begin{array}{ll}
\text{src}_0 \doteq \text{loop\_r}[0] \wedge p_6x + p_7y + p_8 \geq 0, & t_0 \doteq \text{loop\_t}[0], \\
\text{src}_1 \doteq \text{loop\_r}[1] \wedge p_6x + p_7y + p_8 \geq 0, & t_1 \doteq \text{loop\_t}[1] \wedge y' = p_0x + p_1y + p_2, \\
\text{src}_2 \doteq \text{loop\_r}[2] \wedge p_9x + p_{10}y + p_{11} + p_9 \geq 0, & t_2 \doteq \text{loop\_t}[2], \\
\text{src}_3 \doteq \text{loop\_r}[3] \wedge p_9x + p_{10}y + p_{11} \geq 0, & t_3 \doteq \text{loop\_t}[3], \\
\text{src}_4 \doteq \text{loop\_r}[4] \wedge p_9x + p_{10}y + p_{11} \geq 0, & t_4 \doteq \text{loop\_t}[4] \wedge y' = p_3x + p_4y + p_5, \\
\text{src}_5 \doteq \text{loop\_r}[5] \wedge p_6x + p_7y + p_8 + p_6 \geq 0; & t_5 \doteq \text{loop\_t}[5].
\end{array}$$

We introduced two parametric inequalities:  $p_6x + p_7y + p_8 \geq 0$  at index 1 and  $p_9x + p_{10}y + p_{11} \geq 0$  at index 4. Then, we propagated the inequalities backward

exploiting the assignments to  $x$  and  $y$  of  $loop\_t$ . In particular, in  $loop\_t[0]$  and  $loop\_t[3]$  both  $x$  and  $y$  must remain constant. In  $loop\_t[2]$  and  $loop\_t[5]$ , instead,  $y$  remains constant and  $x$  increases by 1. Therefore,  $p_9x + p_{10}y + p_{11} \geq 0$  in  $src_3$  implies that  $p_9x + p_{10}y + p_{11} + p_9 \geq 0$  must hold in  $src_2$  and similarly  $p_6x + p_7y + p_8 \geq 0$  in  $src_0$  implies  $p_6x + p_7y + p_8 + p_6 \geq 0$  at  $src_5$ . We remark that exploiting the equalities in the transition relations is an optimisation we employ to reduce the number of parameters and has no effect on the correctness of the approach.

Now, we need to identify an assignment to the parameters  $p_0, \dots, p_{11}$  such that the funnel-loop template satisfies all hypotheses of Def. 1, Def. 2 and Th. 1. The procedure generates this synthesis problem at line 4 and it searches for a solution (assignment to the parameters) at line 5. The synthesis problem requires the funnel-loop to be reachable in  $Ex$  (FF.1), hence also not empty. We ensure this by requiring the first region of the funnel-loop to contain the last state of the prefix, hence the state  $f_0, f_1, pc = 3, x = 1, y = 1$  must be in  $src_0$ . Then, the funnel-loop must never encounter a deadlock (F.1). This is true by construction of the transition relations of the funnels, because every  $t_i$  is left-total for every assignment to the parameters. We need the funnels to be correctly chained (FL.1, FL.2) and to underapproximate the transition relation  $T$  of  $Ex$  (FF.3). We defined the destination regions as the set of states reachable from the source region in one step. Therefore, we require the following to hold:

$$\exists P \forall V : src_i(V, P) \wedge t_i(V, V', P) \rightarrow src_{(i+1)\%6}(V', P) \wedge T(V, V')$$

Finally, every state in  $src_0$  is a fair state, hence every path through the funnel-loop template is a fair path of  $Ex$  (FF.2).

The following assignment to the parameters satisfies all these requirements:  $p_0 = 0, p_1 = -1, p_2 = 0, p_3 = 0, p_4 = -1, p_5 = 0, p_6 = 1, p_7 = -1, p_8 = 0, p_9 = 1, p_{10} = 1, p_{11} = 0$ . We can substitute these values in the funnel-loop template and obtain the following funnel-loop.

$$\begin{aligned} src_0 &\doteq loop\_r[0] \wedge x \geq y, & t_0 &\doteq loop\_t[0], \\ src_1 &\doteq loop\_r[1] \wedge x \geq y, & t_1 &\doteq loop\_t[1] \wedge y' = -y, \\ src_2 &\doteq loop\_r[2] \wedge x \geq -y, & t_2 &\doteq loop\_t[2], \\ src_3 &\doteq loop\_r[3] \wedge x \geq -y, & t_3 &\doteq loop\_t[3], \\ src_4 &\doteq loop\_r[4] \wedge x \geq -y, & t_4 &\doteq loop\_t[4] \wedge y' = -y, \\ src_5 &\doteq loop\_r[5] \wedge x \geq y; & t_5 &\doteq loop\_t[5]. \end{aligned}$$

Notice that in this process the parametric expressions allowed us to identify an underapproximation of the transition relation of  $Ex$  that toggles the sign of  $y$  instead of allowing any possible assignment. In addition, the parametric inequalities restricted the regions we obtained from the candidate loop to only the states in which  $x \geq |y|$ , hence ensuring that the loop condition  $x^2 \geq xy$  of our example holds. In fact,  $x^2 \geq xy$  is redundant in  $src_0$  and  $src_3$ ; it is implied by  $x \geq y \wedge y > 0$  in the first region and by  $x \geq -y \wedge y < 0$  in the second one. Therefore, this funnel-loop is equivalent to the one we defined in §5.3.

## 7.2. Candidate fair loops: representation and enumeration

We identify lasso-shaped paths in the abstract space built by the assignments  
 985 to a finite set of predicates: two states that agree on the truth assignment for  
 all such predicates correspond to the same abstract state. We then represent  
 the fair loop as a sequence of transitions and regions (sets of states) that under-  
 approximate the transition relation of  $M$ .

Given a fair transition system  $M \doteq \langle V, I^M, T^M, F^M \rangle$  we describe a candi-  
 date fair loop of length  $n$  for  $M$ , associated with an  $E$ -component  
 $H \doteq \langle V, I^H, T^H \rangle$  over regions  $\mathcal{R} \doteq [R_i]_{i=0}^{n-1}$ , assumptions  $\mathcal{A} \doteq [A_i]_{i=0}^{n-1}$ , ranking func-  
 tions  $\text{RF} \doteq [\text{RF}_i]_{i=0}^{n-1}$  and responsible for symbols  $V^H \subseteq V$ , as a sequence of re-  
 gions  $\text{loop}_r \doteq [\text{loop}_r \cdot r_i(V)]_{i=0}^{n-1}$ , transitions  $\text{loop}_t \doteq [\text{loop}_t \cdot t_i(V, V^{\neq H'})]_{i=0}^{n-2}$  and an  
 initial state  $\mathbf{v}_0$ , where  $V^{\neq H} \doteq V \setminus V^H$ . Such that: (i)  $\mathbf{v}_0 \models \text{loop}_r \cdot r_0 \wedge I^H$ , (ii)  
 $\mathbf{v}_0$  is reachable in  $M$ , (iii) the conjunction of a  $\text{loop}_r \cdot r_i$  and the corresponding  
 restricted region  $R_i \wedge A_i$  underapproximates the fair states

$$\exists i \forall V : \text{loop}_r \cdot r_i \wedge R_i \wedge A_i \rightarrow F^M,$$

and (iv) for each step, the conjunction of  $\text{loop}_t \cdot t_i$  and the transition relation  $T^H$   
 of  $H$  is an implicant for a transition in  $M$

$$\begin{aligned} \forall i, V, V' : & (\text{loop}_r \cdot r_i \wedge R_i \wedge A_i \wedge \text{loop}_t \cdot t_i \wedge T^H \wedge \\ & ((\mathbf{0} < \text{RF}_i \wedge R'_i) \vee (\text{RF}_i = \mathbf{0} \wedge R'_{i+1}))) \rightarrow T^M. \end{aligned}$$

Without loss of generality, and to simplify the presentation, we assume the  
 990 fair region to be the first one. The structure of a candidate loop resembles a  
 funnel-loop. However, candidate loops are not guaranteed to satisfy all required  
 hypotheses. In particular, the transitions  $\text{loop}_t \cdot t_i \wedge T^H$  could admit deadlocks  
 (Hyp. F.1) and they are not guaranteed to map every state in the previous region  
 into some state in the following one (Hypotheses FL.1 and FL.2). In addition,  
 995  $H$  may not provide all the required ranking functions. For this reason, in order  
 to identify a funnel-loop, we look for a strengthening of the candidate loop that  
 also satisfies these conditions.

The enumeration of candidate loops and compositions is performed by Alg. 2.  
 The procedure is based on Bounded Model Checking (BMC) [15], for the enu-  
 1000 meration of candidate paths, and on the computation of an underapproximation  
 of  $M$  for each path. The function ENCODE-L2S-FAIR-ABSTRACT-LOOP (line 1)  
 encodes the search for a fair lasso-shaped path in the intersection of  $M$  and the  
 composition of a subset of  $\mathcal{H}$  into a reachability problem given by  $\langle V, I, T, \text{bad} \rangle$ .  
 The problem requires us to identify paths over the variables  $V$ , starting in  $I(V)$   
 1005 and following the steps given by  $T(V, V')$  that end in some state in  $\text{bad}(V)$ . We  
 obtain this encoding via a liveness-to-safety [8] construction that transforms the  
 problem of identifying an abstract lasso into a reachability problem. The loop-  
 back state is identified in the abstract space defined by the predicates in the  
 $E$ -components and in the transition relation and fairness condition of  $M$ . The  
 1010 last state and the loop-back state of the abstract lasso must agree on the truth

assignment of all such predicates, hence they may not be the very same assignment. In the encoding, a set of fresh Boolean variables selects the  $E$ -components to be considered, and the path must be such that at most one ranking function decreases at a time. We then rely on a SMT-solver to identify fair lasso paths of increasing length  $k$  (line 2), as done for the abstract liveness-to-safety algorithm of [10]. The models of this BMC unrolling describe a path in the language of both  $M$  and the composition of a subset of the  $E$ -components in  $\mathcal{H}$ . If  $\mathcal{H}$  is empty or none of the hints is selected, GET-CANDIDATE-COMPOSITION (line 7) returns the trivial hint  $H$  of length equal to the number of states in the abstract lasso. Instead, if some hints are selected,  $H$  is given by their composition projected over the ordered sequence of regions visited by the path. The selected  $E$ -components might not be compatible, for this reason, after extracting the candidate composition at line 7 from the BMC model, GET-COMP-ERROR (line 8) checks if each transition in the composition is compatible (the trivial hint is trivially compatible). If this is not the case, a conflict predicate representing the transitions that are not compatible is used by REMOVE-CONFLICT to refine

the reachability problem  $\langle V, I, T, bad \rangle$  such that we avoid generating the same conflict again. If  $H$  is a valid  $E$ -component the function UNDERAPPROXIMATE (line 12) computes two sequences of  $n - 1$  formulae:  $loop\_r \doteq [loop\_r_i(V)]_{i=0}^{n-2}$  and  $loop\_t \doteq [loop\_t_i(V, V')]_{i=0}^{n-2}$  such that each  $loop\_r_i \wedge loop\_t_i$ , together with  $H$ , underapproximates the transition relation of  $M$ . The function computes an implicant for the formula  $query$  such that the assignments of the lasso described by  $model$  satisfy both formulae. We then partition, for each step  $i$ , the predicates in the implicant into two sets. All predicates containing only symbols of  $V$  at step  $i$  are in  $loop\_r_i$ , while the predicates containing symbols from  $V \cup V'$  at step  $i$  are in  $loop\_t_i$ . Therefore, we split the predicates used to describe the regions from the ones that constrain the transitions. We use  $loop\_r_i$  and  $loop\_t_i$  as formulae meaning the conjunction of all the predicates in the set and they, together with  $H$ , describe the candidate fair loop.

Then, at line 13, we try to synthesise a ranking function for such candidate loop via the method RANK-LOOP. In the literature there are many approaches for the synthesis of ranking functions [16, 17, 18], here we simply assume we are given a method that returns the representation of a ranking function  $rf$  proving the termination of a candidate loop. If the procedure succeeds in identifying a ranking function, the reachability problem  $\langle V, I, T, bad \rangle$  is refined such that we avoid enumerating other loops ranked by the same function, as described in [10]. This is achieved by calling REMOVE-RANKED-LOOPS at line 15). Otherwise, at line 17, GET-PREFIX extracts from  $model$  the prefix of the loop; i.e. the path of  $M$  ending in the the loop-back state. The prefix represents a witness for the reachability of the first region of the candidate loop in  $M$  and the procedure returns it together with the current candidate loop, at line 18. If no candidate loop of length  $k$  exists, we clear the list of refinements and enumerate the candidate loops of length  $k + 1$ .

*Example.* We now provide a brief example on the computation of the under-approximation of  $M$  described by  $loop\_r$  and  $loop\_t$ . Assume the transition relation of  $M$  is  $T \doteq (a \leq 1 \rightarrow b' > b) \wedge (a \geq 2 \rightarrow b' < b)$ , and the loop described by  $model$  is given by the assignments  $a_0 = 1, b_0 = 0, a_1 = 2, b_1 = 1$  and  $a_2 = 0, b_2 = 0$ . Three steps of  $M$  are represented by the formula  $T(V_0, V_1) \wedge T(V_1, V_2)$ . An implicant for such formula satisfied by  $model$  is given by  $\{a_0 \leq 1, b_1 > b_0, a_1 \geq 2, b_2 < b_1\}$ . Such an implicant can be obtained, for example, by applying the techniques presented in [19, 20]. Finally, we partition this set into  $loop\_r$  and  $loop\_t$  by defining their components as follows:  $loop\_r_0 \doteq a \leq 1$ ,  $loop\_t_0 \doteq b' > b$ ,  $loop\_r_1 \doteq a_1 \geq 2$  and  $loop\_t_1 \doteq b' < b$ .

### 7.3. Funnel-loop templates

We call funnel-loop template a candidate funnel-loop whose predicates contain symbols of both  $V$  and a set of parameters  $P$  ( $P$  and  $V$  are disjoint). For each candidate fair loop we generate a sequence of such templates and try to identify an assignment to the symbols  $P$  such that by replacing them with the identified values we obtain a funnel-loop satisfying all the required hypotheses. In the following, the function called NEW-PARAM-EXPR generates

expressions over the symbols  $V$  and the parameters  $P$ , e.g. affine linear functions  $p_0 + \sum_{i=1}^{|V|} p_i v_i$ , where  $|V|$  is the number of symbols in  $V$  and for all  $i$ ,  $p_i \in P$  and  $v_i \in V$ . The function introduces as many parameters as necessary to generate the required expressions.

27: end for

```

---

1075 Alg. 3 shows the procedure we use to generate funnel-loop templates from a candidate loop. We generate templates of the same length as the candidate loop. Function HEURISTIC-PICK-NUM-INEQS (line 1) selects a list of natural numbers to be used to generate the funnel-loop templates. Each number corresponds to the amount of parametric inequalities added to each region of the candidate  
1080 loop to define the corresponding source region of a funnel template (line 7). The higher the number the more freedom will the template have in shrinking the regions, but in the search problem we will have more parameters and a larger space to explore. Notice that, since the first region of the candidate loop is fair by construction, then the last destination region in the funnel-loop  
1085 template will be fair and Hyp. FF.2 holds. We create the  $i^{\text{th}}$  funnel of the funnel-

loop template (lines 6–25) as a restriction of the conjunction of the  $i^{\text{th}}$  region and transition of the candidate loop. In addition, the only nondeterministic component in  $t$  is given by the transition relation of  $H$ . All other components of the transition relation  $t$  of the funnel are a deterministic functional assignment as follows. Let  $V^H$  be the symbols for which  $H$  is responsible. For each symbol  $v_{i+1} \in V_{i+1} \setminus V_{i+1}^H$ , if  $\text{loop\_}t_i$  already contains a functional assignment for  $v_{i+1}$ , then we use that (line 17). Otherwise, we generate a functional assignment for  $v_{i+1}$  as a parametric expression over the symbols in  $V_i$  (line 19). The resulting transition relation is total and Hyp. F.1 holds. We define the destination region of a funnel implicitly as the set of states reachable in one step from  $S \wedge \text{RF} = \mathbf{0}$  (line 23), hence Hyp. F.4 holds by construction. Finally, the procedure returns the funnel-loop template associated with the list of parametric funnels and initial state  $\mathbf{v}_0$ . We will ensure that  $\mathbf{v}_0$  is in the first source region of the funnel-loop. Therefore, since  $\mathbf{v}_0$  is reachable in  $M$ , Hyp. FF.1 holds.

*Example.* We now provide an example to illustrate how a funnel is generated in the lines from 7 to 24. In this example we assume the following:  $V \doteq \{a, b, c\}$  is a set of real-valued symbols; NEW-PARAM-EXPR generates affine linear expressions over  $V$  and a set of parameters  $P \doteq \{p_i\}_{i \in \mathbb{N}}$ ; we are constructing a funnel-loop template adding a single predicate to shrink the region ( $\text{ineq} = 1$ );  $\text{loop\_}r[i] \doteq b < c$ ;  $\text{loop\_}t[i] \doteq c' = c \wedge b' > b + a \wedge b' > c$  and the hint  $H$  responsible for  $\{a\}$  has the following components:  $\mathcal{R}[i] \doteq a > 0$ ,  $\mathcal{R}[i + 1] \doteq a > 0$ ,  $\mathcal{A}[i] \doteq \top$ ,  $\text{RF}[i] \doteq \mathbf{0}$  and  $T^H \doteq a' > a$ .

For simplicity, we defined  $P$  as an infinite set. However, in this example we will use 12 parameters  $\{p_i\}_{i=0}^{11}$ ; we will introduce 3 affine parametric expressions each of which requires 4 parameters. The first expression represents an additional inequality for the region, the second one is used to represent the ranking function, and the last one corresponds to the functional assignment of  $b'$  in the transition relation.

Line 7 defines the source region  $\text{src}$  of the funnel as the conjunction of the  $\text{loop\_}r[i]$ , the restricted region of  $H$  and, since  $\text{ineq} = 1$  it introduces a single parametric predicate:  $p_0 + p_1a + p_2b + p_3c \geq 0$ .

$$\text{src}(V, P) \doteq b < c \wedge a > 0 \wedge p_0 + p_1a + p_2b + p_3c \geq 0.$$

The condition at line 8 is false since the ranking function provided by  $H$  is always equal to  $\mathbf{0}$ . The procedure then executes line 11, which introduces a new parametric expression to represent the ranking function:

$$\text{rf}(V, P) \doteq p_4 + p_5a + p_6b + p_7c.$$

We implicitly consider the function equal to the minimal element  $\mathbf{0}$  if  $\text{rf}(V, P) \leq 0$ . Then, line 14 initialises  $t$  from the transition relation of  $H$  as:

$$t \doteq a > 0 \wedge a' > a \wedge ((\text{rf}(V, P) \leq 0 \wedge a' > 0) \vee (0 < \text{rf}(V, P) \wedge a' > 0 \wedge \text{rf}(V', P) \leq \text{rf}(V, P))).$$

The loop starting at line 15 iterates over the symbols in  $\{b, c\}$ . Consider first the symbol  $c$ , in  $loop\_t[i]$  we find the equality  $c' = c$ , hence the condition at line 16 holds and the equality is added to  $t$  as a conjunct. Consider now the symbol  $b$ ,  $loop\_t[i]$  prescribes no equality for  $b'$ , hence a new parametric expression is introduced and added to  $t$  at line 19, let such equality be  $b' = p_8 + p_9a + p_{10}b + p_{11}c$ . Therefore, the final  $t$  is as follows:

$$t \doteq a > 0 \wedge a' > a \wedge ((0 < rf(V, P) \wedge a' > 0 \wedge rf(V', P) \leq rf(V, P)) \vee (rf(V, P) \leq 0 \wedge a' > 0)) \wedge c' = c \wedge b' = p_8 + p_9a + p_{10}b + p_{11}c.$$

Finally,  $dst$  is defined as the set of states that admit a predecessor through  $t$  in  $src$  with  $rf = \mathbf{0}$ :

$$dst(a', b', c', P) \doteq \exists a, b, c : src(a, b, c, P) \wedge rf(a, b, c, P) \leq 0 \wedge t(a, b, c, a', b', c', P).$$

#### 1120 7.4. Funnel-loop synthesis problem

We now describe the  $\exists\forall$  quantified formula that corresponds to the synthesis problem of a funnel-loop template. Alg. 1 computes this formula for every funnel-loop template  $template$  via the method  $ef\_constraints$  at line 4. We search for an assignment to the parameters  $P$  of the funnel-loop template such that by replacing them with the identified values we obtain a funnel-loop that satisfies all hypotheses of Defs. 1, 2 and of Th. 1. In the hypotheses, for every funnel  $fnl_i \doteq \langle S_i, T_i, D_i, RF_i \rangle$ , we replace each destination region  $D_i$  with the quantified formula:

$$D_i(V') \doteq \exists V : S_i(V) \wedge RF_i(V) = \mathbf{0} \wedge T_i(V, V'). \quad (1)$$

Every instance of the funnel-loop template must contain a fair region since  $loop\_r_0$  is a subset of the fair states and  $S_0$ , by construction, underapproximates  $loop\_r_0$ . We ensure that Hyp. FF.1 holds by requiring that  $\mathbf{v}_0$  is in the source region of the first funnel  $fnl_0$  with the constraint:

$$\exists P : S_0(\mathbf{v}_0, P). \quad (2)$$

Hyp. F.1 holds by construction, since the next region implies the assumptions required by the  $E$ -component. Therefore, the transition relation of the  $E$ -component must always allow for a successor for all assignments to the  $V \neq H'$ . In addition, the other components of the transition relation of the funnel describe a functional assignment to the  $V \neq H'$  without any circular dependency. Hyp. F.4 holds since we implicitly defined the destination region of each funnel  $fnl_i$  as the set of states reachable in one step from  $S_i \wedge RF_i = \mathbf{0}$ . Then, we ensure that every instantiation of every funnel template  $fnl_i$  in the funnel-loop template satisfies hypotheses F.2 and F.3 by requiring that the following hold:

$$\exists P \forall V, V' : (S_i(V, P) \wedge \mathbf{0} < RF_i(V, P) \wedge T_i(V, V', P)) \rightarrow S_i(V', P); \quad (3)$$

$$\exists P \forall V, V' : (S_i(V, P) \wedge \mathbf{0} < RF_i(V, P) \wedge T_i(V, V', P)) \rightarrow RF_i(V', P) < RF_i(V, P). \quad (4)$$

The funnels must be correctly chained for hypotheses [FL.1](#) and [FL.2](#) to hold. Notice that in these formulae are implications whose left-hand-side is  $D_i$  and we  
1135 bring the existential quantifier out in front of the formula as a universal quantifier. For Hyp. [FL.1](#) to hold we require every two consecutive funnel templates  $fnl_i$  and  $fnl_{i+1}$  in the funnel-loop template to satisfy the following:

$$\exists P \forall V, V' : (S_i(V, P) \wedge R_{F_i}(V, P) = \mathbf{0} \wedge T_i(V, V', P)) \rightarrow S_{i+1}(V', P). \quad (5)$$

Similarly, considering the first and last funnels  $fnl_0$  and  $fnl_{n-1}$ , for Hyp. [FL.2](#) we require:

$$\exists P \forall V, V' : (S_{n-1}(V, P) \wedge R_{F_{n-1}}(V, P) = \mathbf{0} \wedge T_{n-1}(V, V', P)) \rightarrow S_0(V', P). \quad (6)$$

1140 This ensures that  $D_{n-1}$  is a subset of  $S_0$ . We have observed above that  $S_0$  contains only fair states, hence [FF.2](#) holds. Finally, we require each funnel-loop instance to underapproximate  $M$  (Hyp. [FF.3](#)) by requiring the following to hold for every funnel  $fnl$ :

$$\exists P \forall V, V' : S(V, P) \wedge T(V, V', P) \rightarrow T^M(V, V'). \quad (7)$$

The final synthesis problem is then given by the conjunction of all the constraints (1)–(7). A solution for this problem is a model that assigns a value to  
1145 each symbol in  $P$  such that the formulae hold for all possible assignments to the symbols in  $V \cup V'$ . From one such model we can generate a concrete funnel-loop by substituting the parameters  $P$  with their assignment.

## 8. Related work

1150 Most of the literature in verification of temporal properties of infinite-state transition systems, hybrid automata and termination analysis focuses on the universal case, while the existential one has received relatively little attention.

Most closely related are the works concerned with proving *program non-termination*. The works [\[21\]](#) and [\[4\]](#) are based on the notion of closed recurrence set, that corresponds to proving the non-termination of a relation. Instead, the  
1155 works [\[22\]](#) and [\[23\]](#) search for non-terminating executions via a sequence of safety queries. Other approaches look for specific classes of programs ([\[24\]](#) and [\[25\]](#) prove the decidability of termination for linear loops over the integers), or specific non-termination arguments (in [\[26\]](#) non-termination is seen as the sum  
1160 of geometric series). However, none of these works deals with fairness and they rely on the existence of a control flow graph, whereas we work at the level of transition system.

The work [\[27\]](#) reduces the verification of the universal fragment of CTL on an infinite-state transition system to the problem of deciding whether a program  
1165 always returns true. The approach can be applied also on LTL properties by relying on a reduction based on prophecy variables and it relies on some off-the-shelf tool for the analysis of the program. Therefore, its capability of proving

or identifying a counterexample for some property depends on the ones of the considered underlying tool.

1170 The work [28] explicitly deals with fairness for infinite-state programs and supports full CTL\*; it is able to deal with existential properties and to provide fair paths as witnesses. The approach focuses on programs manipulating integer variables, with an explicit control-flow graph, rather than more general symbolic transition systems expressed over different theories (including real arithmetic).  
1175 Another approach supporting full CTL\* is proposed in [29]. The work presents a model checking algorithm for the verification of CTL\* on finite-state systems and a deductive proof system for CTL\* on infinite-state systems. In the first case the authors reduce the verification of CTL\* properties to the verification of properties without temporal operators and a single fair path quantifier in front  
1180 of the formula. To the best of our knowledge there is no generalisation of this algorithm, first reported in [30] and then also in [31], to the infinite state setting. The rules presented in the second case have been exploited in [32] to implement a procedure for the verification of CTL properties, while our objective is the falsification of LTL properties. Moreover, in these settings ([28], [29]) there is  
1185 no notion of non-zenoness.

The works on *timed automata* are less relevant: although the concrete system may exhibit no lasso-shaped witnesses, due to the divergence of clocks, the problem is decidable, and lasso-shaped counterexamples exist in finite bisimulating abstractions. This view is adopted, for example, in UPPAAL [33].  
1190 Other tools directly search for non lasso-shaped counterexamples, but the proposed techniques are specific for the setting of timed automata [34, 12] and lack the generality of the method proposed in this paper.

Our approach can be applied also to *hybrid systems*. Most of the works in this context are concerned with the verification of safety properties [35].  
1195 Instead, we deal with the falsification of general LTL, liveness properties. The works [36] and [37] propose a general approach for the verification of LTL properties on such systems. However, they can only identify lasso-shaped counterexamples and lack the generality of the approach we present in this work. Other approaches consider only particular types of liveness properties or impose additional restrictions on the model. The technique presented in [38] considers only stability properties and [39] falsifies properties under robustness assumptions, while [40] considers robust discrete time systems. In [41] the authors propose a technique to falsify LTL properties via randomised search, however  
1200 it is restricted to safety LTL and does not consider *Zeno* paths.

1205 *Inductive Reachability Witness* (IRW), defined in [14], is a structure roughly equivalent to our definition of funnel. [14] proposes to identify a single IRW as a witness for reachability queries in imperative programs over real variables: hence as a compact representation of a finite path. Instead, we look for a sequence of funnels, in the form of a funnel-loop, that represents an infinite path for an  
1210 infinite-state fair transition system.

Finally, the verification conditions we identify in this work for the search of a funnel-loop can be expressed in the form of *existentially-quantified constrained*

*Horn-like clauses* (E-CHCs) [32].<sup>7</sup> E-CHCs are an extensions of *constrained Horn clauses* (CHCs) [42, 43, 44] with existential quantifiers. The two formalisms have been proposed as means to decouple the definition of verification problems from the actual solving algorithm. This enables the separation of the proof methodology from the procedures used to address the problem. Unfortunately, we were not able to obtain any tool capable of identifying solutions to E-CHCs, hence we could not investigate this direction any further.

## 9. Experimental Evaluation

This section first presents our implementation of the approach (9.1), then describes the benchmarks we used (9.2) and briefly presents the other state-of-the-art tools we considered (9.3), finally it reports the setup, the results and the discussion of the experimental evaluation we performed (9.4).

### 9.1. Implementation

We have implemented these procedures in a prototype, called F3<sup>8</sup> (for FIND-FAIRFUNNEL), written in Python. F3 uses MATHSAT5 [45] and Z3 [46] as underlying SMT engines, interacting with them through PYSMT [47]. SMT-solvers sometimes take a very long time on a single query. For this reason we associate a timeout to each call to SMT-SOLVE. If the solver is unable to answer within the given time F3 assumes unknown as result and continues. F3 takes as input a transition system  $M$ , a fairness condition  $F$  and a possibly empty set of  $E$ -components  $\mathcal{H}$ , and tries to identify a funnel that proves that  $M$  admits at least one path that visits  $F$  infinitely-often. We then employ the usual tableau construction to support LTL specifications via reduction to the previous case. In order to support timed systems, we use the product construction described in [37] to remove all Zeno-paths of the model. F3 enumerates funnel templates in increasing order of complexity. By default, F3 considers a minimum of 0 and a maximum of 2 inequalities in the implementation of HEURISTIC-PICK-NUM-INEQS of Alg. 3. F3 considers only simple ranking functions corresponding to the PR-ranking template described in [16] which are simple affine linear functions. Such ranking functions are used in the definition of the funnel templates and when trying to identify a ranking function for a candidate abstract loop in Alg. 2. In addition, we only synthesise predicates in the form of affine linear equalities or inequalities; the implementation of the function NEW-PARAMETRIC-EXPR in F3 generates affine linear expressions. An important optimization is that F3 generates ranking function templates (line 11 of Alg. 3) only when it finds a pair of abstract states that prescribe the same assignment to the Boolean variables of  $M$ ; if the abstract states differ in their Boolean variables,  $rf$  is simply set

<sup>7</sup>Appendix A reports an encoding for the funnel-loop search problem in E-CHCs and proves it to be both sound and complete.

<sup>8</sup>the tool and the benchmarks can be downloaded from <https://github.com/EnricoMagnago/F3>

1250 to the constant  $\mathbf{0}$ . This avoids the introduction of unnecessary parameters for  
funnels which do not need an explicit ranking function. F3 solves the param-  
eter synthesis problem described in Sec. 7 via a combination of the EF-SMT  
procedure of [48] and the application of Motzkin’s transposition theorem [49]  
to reduce the problem into a purely existentially-quantified one which can then  
1255 be solved via standard quantifier-free SMT reasoning: we first try to apply EF-  
SMT, and resort to the elimination of universal quantifiers only if this fails to  
provide a definite answer. Finally, when applying the Motzkin’s transposition  
theorem, F3 replaces non-linear terms with fresh symbols, in order to obtain  
a linear system. This simple way of handling non-linearities has the benefit of  
1260 being very easy to implement; on the other hand, however, it can produce very  
coarse approximations, which can prevent F3 from finding counterexamples in  
cases where non-linearities play a significant role. A possible approach to handle  
non-linearities in a more precise manner is described in [14].

### 9.2. Benchmarks

1265 In order to evaluate the effectiveness of our method, we have evaluated F3  
on a wide range of benchmarks coming from different domains, from software  
(non)termination to timed automata and infinite-state symbolic transition sys-  
tems. More specifically, we considered a total of 455 benchmarks, divided into  
6 categories:

1270 **LS** consists of 52 nonterminating linear software benchmarks taken from the C  
programs of the software termination competition [50];

**NS** contains 30 nonlinear software programs, of which 29 have been taken from  
[4] and one we defined;

1275 **ITS** are 70 LTL falsification problems on infinite-state systems; 2 of such prob-  
lems are proof obligations generated in the verification of a contract-based  
design, 29 come from the scaling to up to 30 processes of a model of the  
bakery mutual exclusion protocol in which we introduced a bug, other 29  
come from the scaling to up to 30 processes of a semaphore-based syn-  
chronisation protocol, and the last 10 are instances we created;

1280 **TA** contains 174 LTL falsification problems on timed automata; we consider 6  
different protocols taken from [51] (*critical*, *csma*, *fddi*, *fischer*, *lynch* and  
*train*) and scale each of them from 1 to 30 processes;

**TTS** consists of 120 LTL falsification problems on timed transition systems,  
of which 116 come from the scaling from 1 to 30 processes of 4 protocols  
1285 (inspired by the *csma*, *fischer*, *lynch* and *token ring* protocols), and 4  
are handcrafted instances. The 4 protocols are a subset of the ones we  
considered in the TA instances. However, in this case we have extended  
them to obtain models that cannot be represented as timed automata. For  
the *csma* protocol we introduced an adaptive backoff time for each process  
1290 that increases every time a station encounters a collision and decreases

each time it successfully communicates the whole message. We extended the *fischer* and *lynch* protocols by allowing each process to propose a wait time, then the actual waiting time used to ensure mutual exclusion is the maximum of the proposed values. Finally, in the *token ring* protocol we added a stopwatch variable that keeps track of the total amount of time spent while transmitting and we ask to verify whether such value is bounded by 10 subject to a fairness assumption on the token manager of the protocol.

**HS** are 9 LTL falsification problems on hybrid systems (encoded as nonlinear infinite-state transition systems), 5 of which have been taken from the ARCH competition [52] and 4 are models of a bouncing ball which differ on the behaviour of the bounce.

F3 only handles symbolic transition systems, and not software programs; therefore, we have encoded the software benchmarks as infinite-state transition systems by introducing an explicit program counter as state variable. Moreover, since F3 only supports systems with Boolean, integer and real variables, we have not considered programs that involve recursion or dynamic memory allocation.

### 9.3. Competitor tools

We compare F3 with the following state-of-the-art tools: ANANT [4], APROVE [53], DIVINE3 [54], IRANKFINDER [55], MITLBMC [56], NUXMV [12], T2 [57], ULTIMATE [58] and UPPAAL [59]. Unfortunately we could not obtain the software described in [32] to solve E-CHC problems. Most of the other tools are not able to handle all the benchmarks we have considered. Therefore, we limit their application as follows:

- we ran ANANT, APROVE, IRANKFINDER and T2 only on the software nontermination problems (LS and NS groups);
- we ran DIVINE3, MITLBMC and UPPAAL only on the timed automata (TA) benchmarks; moreover, since UPPAAL supports only a fragment of LTL which is not sufficient to express the properties of the *fischer* and *lynch* benchmarks, we could run it only on 116 of the 174 TA instances;
- as ULTIMATE doesn't support non-linear arithmetic, we didn't run it on the NS family. Moreover, since it supports LTL specifications but works on programs rather than transition systems, we translated the benchmarks to LTL verification problems on software programs, using the same approach described in [10].
- NUXMV is the only other tool (besides F3) that supports all the benchmarks. Our focus is falsification of universal properties (or dually verification of existential ones), hence we ran NUXMV using only its BMC engine. The other algorithms available in NUXMV have no additional falsification capabilities and also try to verify the property.

Table 1: Summary of experimental results (number of solved instances per benchmark family).

Benchmark family	F3 (no hints)	Anant	AProVe	DiVinE3	iRankFinder	MITLBMC	nuXmv	T2	Ultimate	Uppaal
<b>LS (52)</b>	<b>52</b>	38	43	-	39	-	28	38	49	-
<b>NS (30)</b>	<b>30</b>	25	5	-	6	-	14	2	-	-
<b>ITS (70)</b>	<b>67</b>	-	-	-	-	-	4	-	8	-
<b>TA (174)</b>	130	-	-	43	-	<b>151</b>	90	-	0	103
<b>TTS (120)</b>	<b>50</b>	-	-	-	-	-	8	-	1	-
<b>HS (9)</b>	<b>4</b>	-	-	-	-	-	0	-	-	-
<b>Total (455)</b>	<b>333</b>	63	48	43	45	151	144	40	58	103

Entries marked with “-” denote that the tool cannot handle the given benchmarks.

#### 9.4. Evaluation

We executed each tool on the corresponding benchmarks on a machine running Ubuntu 20.04 equipped with an Intel(R) Xeon(R) Gold 6226R 2.90 GHz CPU, using a 1 hour timeout and a memory limit of 30 GB for each benchmark. A summary of the evaluation results is reported in Table 1. We run F3 on those benchmarks without providing any hint and the table shows, for each tool, the number of solved instances in each benchmark family. When a tool is not applicable to a specific family, this is marked with “-”. From the table, we can see that F3 solved the highest number of instances overall and also the highest number of instances in all categories with the exception of timed automata. In this category F3 is outperformed only by MITLBMC, which implements a technique explicitly developed for timed automata. This demonstrates the generality of our approach, although (unsurprisingly) it is possible to define more efficient procedures to target specific classes of problems. F3 successfully identifies a fair path in all nonlinear software benchmarks and also in 4 of the hybrid (nonlinear) systems. Therefore, while being coarse-grained, the approximation of the nonlinear terms used by F3 appears to be sufficient in these cases. Finally, we should remark that the competitor tools (with the exception of MITLBMC and NUXMV in BMC mode) are also able to prove that a universal property holds, whereas F3 can only find counterexamples. On the other hand, however, our techniques can be easily integrated with approaches focusing on proving properties, such as [10, 37].

We then considered the 5 hybrid benchmarks that F3 failed to solve without hints. In 4 cases the definition of a single hint is sufficient to allow F3 to identify a fair path. The remaining benchmark is a handcrafted one representing a bouncing ball such that the interval of time between consecutive bounces follows the harmonic series and the tool is required to identify a non-Zeno path in which the ball keeps bouncing forever. We know that the harmonic series

diverges, hence such a path exists. However, the path does not have the finite-  
1360 variability property, often assumed in real-time temporal logics (e.g. [60, 61]);  
there is no bound on the number of times predicates change truth assignment  
for any finite interval of time: there is no lower bound on the time between  
two bounces. In addition, the absence of such bounds hinders the definition  
of simple ranking functions, since they require a minimum constant progress  
1365 at every transition. We remark that the HS instances are the most complex  
ones, they involve both nonlinearities and timing constraints. The definition  
of the hints for such complex systems requires in depth analysis of each model  
and also an understanding of the features that the automated procedure could  
struggle to analyse. However, the integration of the hints within an automatic  
1370 procedure allows the user to focus on the few hardest components of the model,  
while relying on the automated procedure to analyse the relatively simpler ones.  
Therefore, it provides an additional possibility to be explored to analyse the  
system before resorting to a purely manual inspection. Our experiments, while  
relatively limited in number, showed this approach to be viable allowing the  
1375 procedure to identify 4 additional counterexamples on complex instances that  
no other tool managed to address successfully.

We conclude with some general observations about F3. F3 identifies funnel-  
loops by trying to instantiate a number of templates. As in every template-  
based approach, this implies that it will fail to identify funnel-loops that do  
1380 not match the considered templates. For example, F3 generates the templates  
by strengthening the candidate loops with affine expressions and inequalities,  
hence it will fail to identify funnel-loops that require the procedure to identify  
nonlinear assignments or constraints. In our experiments this issue has been  
mitigated by the fact that the candidate loop itself might provide the necessary  
1385 nonlinear terms, hence F3 does not need to synthesise them. F3 employs sym-  
bolic reasoning and inherits the instability typical of this kind of techniques that  
deal with undecidable problems. The execution time of F3 is greatly affected  
by the order in which the candidate loops are explored. For each candidate  
loop for which it fails to identify a ranking function, F3 generates and tries to  
1390 instantiate a number of funnel-loop templates. The number of these templates  
can be relatively large and, in our experiments, F3 spent most of the time in  
trying to instantiate them. For this reason, the execution time of F3 might  
change significantly depending on the order in which the SMT-solvers identify  
candidate loops. F3 tries to mitigate this problem by analysing the templates in  
1395 increasing order of complexity and by applying heuristics normalizations on the  
expressions before calling the SMT-solver. In principle each funnel-loop tem-  
plate can be analysed independently from the others and performing such tasks  
in parallel could mitigate this issue; in addition, one could also analyse different  
candidate loops in parallel. However, we did not explore this possibility and our  
1400 prototype does not employ any kind of parallelism.

## 10. Conclusions

In this work we presented an approach to automatically verify existential properties on infinite-state fair transition systems which can also benefit from some user-defined hints. The witness for the existential property is given as a sequence of funnels and can represent paths that do not have a lasso-shape structure. We evaluated a prototype implementation of the approach on a wide variety of benchmarks. The prototype is effective and able to address verification tasks successfully in many different domains. However, there are still some classes of problems that exhibit behaviours that are outside the scope of our prototype, as we have seen in the case of the harmonic bouncing ball.

In the future, we plan to improve the procedure by automating the system decomposition and by investigating different heuristics for the selection of funnel-loop templates and to better exploit the system decomposition. Another interesting direction is to improve the support for nonlinear expressions, e.g. it should be possible to integrate the technique presented in [14] in our procedure. Finally, we plan to integrate our procedure with dual approaches used to verify LTL properties.

## Appendix A. Encoding of funnel-loop search in E-CHC

We described the funnel-loop synthesis problem using exist-forall quantified First-Order Logic formulae and defined an ad-hoc procedure to address this problem. In the literature it is possible to find formalism meant to decouple the definition of the verification problem and the actual solving algorithm: they separate the proof methodology from the procedures used to address the problem. One such formalism is *Constrained Horn clauses* (CHCs) [42, 43, 44], for which off-the-shelf solvers have been developed. In the following, we consider an extension of CHCs, namely *existentially-quantified constrained Horn-like clauses* (E-CHCs) [32]. E-CHCs are expressive enough to represent the funnel-loop synthesis problem, hence allow an alternative representation of our synthesis problem. However, possibly due to the complexity of solving such problems in general, there is a lack of tools capable of identifying solution for E-CHCs. Therefore, the encoding in E-CHCs has no impact on the theoretical and experimental results we present in this work. We believe that representing the problem in a common framework to describe verification tasks could provide a better perspective on how the approach and techniques we propose in this work fit into the broader context of formal verification.

For the syntax and semantics of E-CHCs we refer to [42]. In the following we present a sound and complete encoding for the search problem of a funnel-loop of length one in E-CHCs. It is possible to define a similar E-CHC encoding that also considers a set of user-defined *E*-components as hints, similarly to the procedure described in Sec. 7. However, such encoding is rather complex and does not provide any additional contribution to our discussion since we were not able to obtain any tool capable of identifying solutions for E-CHCs.

Let  $M \doteq \langle V, I^M, T^M, F^M \rangle$  be a fair transition system and let  $R(c, V)$ ,  $T(V, V')$  and  $Rank(V, V')$  be query symbols, where  $c$  is a fresh Boolean symbol ( $c \notin V$ ). A solution to the E-CHC problem below is an interpretation for  $R$ ,  $T$  and  $Rank$  satisfying all its formulae.  $R$  represents the source region, and  $c \wedge R(c, V)$  underapproximates the fair states. Th. 7 shows that any solution to the E-CHC below corresponds to a funnel-loop and Th. 8 shows that if  $M$  admits a funnel-loop then there exists an interpretation for the query symbols satisfying the following E-CHC. Therefore, the encoding is sound (Th. 7) and relatively complete (Th. 8). While it is possible to represent in E-CHC the search of a funnel-loop of arbitrary length  $n$ , Th. 2 ensures that looking for funnel-loops of length one is sufficient.

$$\top \rightarrow \exists c, V : R(c, V) \wedge I^M(V) \quad (\text{A.1})$$

$$T(V, V') \rightarrow \exists c : R(c, V') \quad (\text{A.2})$$

$$R(c, V) \wedge T(V, V') \rightarrow T^M(V, V') \quad (\text{A.3})$$

$$R(c, V) \rightarrow \exists V' : T(V, V') \quad (\text{A.4})$$

$$c \wedge R(c, V) \rightarrow F^M(V) \quad (\text{A.5})$$

$$\neg c \wedge R(c, V) \wedge T(V, V') \rightarrow \text{Rank}(V, V') \quad (\text{A.6})$$

$$\text{dwf}(\text{Rank}) \quad (\text{A.7})$$

Let  $Cex \doteq \langle V, \exists c : R(c, V), T(V, V'), \top \rangle$  be the transition system associated with an interpretation of the query symbols of the E-CHC above. Eq. (A.1) requires the existence of some initial state of  $M$  in  $R$ : the set of initial states of  $Cex$  is not empty. Eq. (A.2) ensures that  $T$  can only reach states in  $R$ , and Eq. (A.3) guarantees that in such region  $T$  is an underapproximation of  $T^M$ :  $Cex$  is simulated by  $M$ , hence a path of  $Cex$  is also a path in  $M$ . Eq. (A.4) requires  $T$  to be left-total with respect to  $R$ :  $Cex$  cannot reach a deadlock. Eq. (A.5) requires  $R(\perp, V)$  to be a subset of the fair states of  $M$ . Eq. (A.6) requires the relation  $T(V, V')$  describing pairs of current and next states such that the first one is in  $R(\perp, V)$  to underapproximate some well-founded relation  $\text{Rank}$ . The well-foundedness of  $\text{Rank}$  ensures that there is no infinite chain of states in  $R(\perp, V)$ , hence it must eventually reach a state in  $R(\top, V)$ , hence by Eq. (A.5) must eventually reach a fair state.

**Theorem 7.** *Given a fair transition system  $M \doteq \langle V, I^M, T^M, F^M \rangle$  and an interpretation for the queries  $R, T$  and  $\text{Rank}$  satisfying all Eqs. (A.1)–(A.7). Then there exist a funnel-loop for  $M$ .*

The proof of Th. 7 is reported in [Appendix B.5](#).

**Theorem 8.** *Let  $\text{floop}$  be a funnel-loop of length one for a transition system  $M \doteq \langle V, I^M, T^M, F^M \rangle$ . Then, there exists an interpretation for the query symbols  $R, T$  and  $\text{Rank}$  satisfying all Eqs. (A.1)–(A.7).*

The proof of Th. 8 is reported in [Appendix B.6](#).

## Appendix B. Theorems and proofs

### Appendix B.1. Funnel-loop disjoint regions

In this section we show that for every funnel-loop there exist a corresponding one whose regions are pairwise disjoint and that admits the same paths. Let  $\text{floop} \doteq [fnl_i]_{i=0}^{n-1}$  be a funnel-loop of length  $n$  over symbols  $V$ . We define a corresponding funnel-loop  $\widehat{\text{floop}} \doteq [\widehat{fnl}_i]_{i=0}^{n-1}$  over symbols  $\widehat{V} \doteq V \cup \{l\}$  that admits the same set of paths projected over the symbols  $V$  and whose regions are pairwise disjoint.  $l$  is a fresh symbol ( $l \notin V$ ) we use to keep track of the index of the current region. More formally we have the following:

- $\widehat{V} \doteq V \cup \{l\}$ , where  $l \notin V$  is a fresh symbols whose domain are the integers from 0 to  $n - 1$ .
- $\widehat{S}_i \doteq S_i \wedge l = i$ .
- 1775 •  $\widehat{D}_i \doteq D_i \wedge l = (i + 1)\%n$ .
- $\widehat{R}_{F_i} \doteq R_{F_i}$ .
- $\widehat{T}_i \doteq T_i \wedge (\mathbf{0} < R_{F_i} \wedge l' = l) \vee (R_{F_i} = \mathbf{0} \wedge l' = (l + 1)\%n)$

**Theorem 9.** *Let  $\widehat{floop}$  be a funnel-loop. Then, all  $[\widehat{fnl}_i]_{i=0}^{n-1}$  satisfy the hypotheses of Def. 1 and  $\widehat{floop}$  satisfies the hypotheses of Def. 2.*

1780 *Proof.* We first show that each  $\widehat{fnl}_i$  in  $[\widehat{fnl}_i]_{i=0}^{n-1}$  is a funnel and then show that they are correctly concatenated in  $\widehat{floop}$  hence it is a funnel-loop.

1785 **F.1** By definition  $\widehat{T}_i \doteq T_i \wedge (\mathbf{0} < R_{F_i} \wedge l' = l) \vee (R_{F_i} = \mathbf{0} \wedge l' = (l + 1)\%n)$ . In each state either  $R_{F_i} = \mathbf{0}$  holds or  $\mathbf{0} < R_{F_i}$  does. Therefore, in the first case  $\widehat{T}_i$  admits a successor in such that  $l' = (l + 1)\%n$ , in the second case it admits a successor in which  $l' = l$ . Since Hyp. **F.1** holds for  $fnl_i$ , its transition relation  $T_i(V, V')$  is left-total. Therefore, also  $\widehat{T}_i$  is left-total and Hyp. **F.1** holds for each  $\widehat{fnl}_i$  in  $\widehat{floop}$ .

1790 **F.2** By definition  $\widehat{T}_i \doteq T_i \wedge (\mathbf{0} < R_{F_i} \wedge l' = l) \vee (R_{F_i} = \mathbf{0} \wedge l' = (l + 1)\%n)$ . Therefore, every pair of states  $\langle \widehat{v}, \widehat{v}' \rangle \in \widehat{T}_i$  such that  $\widehat{v} \models \widehat{S}_i$  must be such that they assign the same value  $i$  to  $l$ . Let  $\mathbf{v}$  and  $\mathbf{v}'$  be the projection of  $\widehat{v}$  and  $\widehat{v}'$  to the symbols  $V$ . Then,  $\langle \mathbf{v}, \mathbf{v}' \rangle \in T_i$  and  $\mathbf{v} \models S_i$ . Since, Hyp. **F.2** holds for  $fnl_i$ , then  $\mathbf{v}' \models S'_i$  also holds.  $\mathbf{v}' \models S'_i$  and the fact that  $\widehat{v}'$  assigns  $l$  to  $i$  implies that  $\widehat{v}' \models S'_i$ . Therefore, Hyp. **F.2** holds for  $\widehat{fnl}_i$ .

1795 **F.3** By applying the same reasoning as above, for every such step in  $\widehat{fnl}_i$  we obtain a corresponding step in  $fnl_i$  by projecting the assignments over the symbols in  $V$ . Hyp. **F.3** holds for  $fnl_i$  hence those assignments must decrease the value of the ranking function  $R_{F_i}$ . Therefore, since  $R_{F_i}$  does not depend on  $l$  its value must decrease also in all such steps of  $\widehat{fnl}_i$  and Hyp. **F.3** must hold.

1800 **F.4** By applying the same reasoning as the previous two cases, for every such step in  $\widehat{fnl}_i$  we obtain a corresponding step in  $fnl_i$  by projecting the assignments over the symbols in  $V$ . Hyp. **F.4** holds for  $fnl_i$  hence the second projected state must be in  $D_i$ . By definition of  $\widehat{T}$ , the second state must assign to  $l$  the index of the next region. Such an assignment agrees with the assignment required by  $\widehat{D}_i$ , therefore Hyp. **F.4** holds for  $\widehat{fnl}_i$ .

1805

We now show that  $\widehat{floop}$  is a funnel-loop.

FL.1, FL.2 Each  $\widehat{D}_i$  requires the same assignment to  $l$  as  $\widehat{S}_{(i+1)\%n}$ . Therefore, since hypotheses FL.1 and FL.2 holds for  $floop$ , they must also hold for  $\widehat{floop}$ .

□

1810 **Theorem 10.** *The languages of  $floop$  and  $\widehat{floop}$  admit the same set of paths projected over the symbols  $V$ .*

*Proof.* We show that  $\widehat{floop}$  admits all paths of  $floop$  and vice-versa by induction of their funnels and the length of the path.

1815 • Assume  $floop$  admits a path starting from some state  $\mathbf{v}$ . Then by definition  $\mathbf{v} \models S_i$  for some  $i$ . Let  $\widehat{\mathbf{v}}$  assign  $l$  to  $i$  and agree with  $\mathbf{v}$  on the assignments of all symbols in  $V$ . Then  $\widehat{\mathbf{v}} \models \widehat{S}_i$  and  $\widehat{\mathbf{v}}$  is an initial state for  $\widehat{floop}$ .

1820 Viceversa, assume  $\widehat{floop}$  admits a path starting from some state  $\widehat{\mathbf{v}}$ . Then by definition  $\widehat{\mathbf{v}} \models \widehat{S}_i$  for some  $i$ . Let  $\mathbf{v}$  be its projection over the symbols  $V$ , then  $\mathbf{v} \models S_i$  and is an initial state for  $floop$ .

• Let  $\pi$  be a path of  $floop$  ending in state  $\mathbf{v}$  and  $\widehat{\pi}$  be the corresponding path of  $\widehat{floop}$  ending in  $\widehat{\mathbf{v}}$ . Let  $S_i$  be the region of  $floop$  such that  $\mathbf{v} \models S_i$  and let  $\widehat{S}_i$  be its corresponding region in  $\widehat{floop}$ .

1825 Assume  $floop$  admits a successor state  $\mathbf{v}'$  of  $\mathbf{v}$ . Then either  $\mathbf{v}' \models S'_i$  or  $\mathbf{v}' \models S'_{(i+1)\%n}$ . Let  $\widehat{\mathbf{v}'}$  be the assignment that extends  $\widehat{\mathbf{v}}$  with  $l' = i$  in the first case and  $l' = (i+1)\%n$  otherwise.  $\widehat{\mathbf{v}'}$  is a successor of  $\widehat{\mathbf{v}}$  corresponding to  $\mathbf{v}'$  such that  $\pi$  extended with  $\mathbf{v}'$  corresponds to  $\widehat{\pi}$  extended with  $\widehat{\mathbf{v}'}$ .

1830 Viceversa, assume  $\widehat{floop}$  admits a successor state  $\widehat{\mathbf{v}'}$  of  $\widehat{\mathbf{v}}$ . Let  $\mathbf{v}'$  be the restriction of  $\widehat{\mathbf{v}'}$  to the symbols in  $V$ . Then,  $\mathbf{v}'$  is a successor for  $\mathbf{v}$  such that  $\widehat{\pi}$  extended with  $\widehat{\mathbf{v}'}$  corresponds to  $\pi$  extended with  $\mathbf{v}'$ .

□

### Appendix B.2. $E$ -components disjoint regions

1835 In this section we show that for every  $E$ -component there exist a corresponding one whose regions are pairwise disjoint and that admits the same paths. Given an  $E$ -component  $H \doteq \langle V, I(V), T(V, V') \rangle$  of length  $m$  over regions  $\mathcal{R}$ , assumptions  $\mathcal{A}$ , ranking functions  $\mathcal{W}$  and responsible for  $V_r \subseteq V$ , we define a corresponding  $E$ -component  $\widehat{H} \doteq \langle \widehat{V}, \widehat{I}(\widehat{V}), \widehat{T}(\widehat{V}, \widehat{V}') \rangle$  over regions  $\widehat{\mathcal{R}}$ , assumptions  $\mathcal{A}$ , ranking functions  $\mathcal{W}$  and responsible for  $\widehat{V}_r$  whose regions and pairwise disjoint.  $\widehat{H}$ , with respect to  $H$ , has an additional symbol  $l$  used to keep track of the index of the current region and each region is strengthened by requiring the correct assignment for such symbol, while the sets of assumptions and ranking functions remain the same. More formally we have the following:

- $\widehat{V} \doteq V \cup \{l\}$ , where  $l \notin V$  is a fresh symbols whose domain are the integers from 0 to  $m - 1$ .

- 1845 •  $\hat{V}_r \doteq V_r \cup \{l\}$ .
- $\hat{\mathcal{R}} \doteq \{R_j \wedge l = j \mid R_j \in \mathcal{R}\}$
- $\hat{I}(\hat{V}) \doteq I(V) \wedge \bigwedge_{j=0}^{m-1} l = j \rightarrow R_j(V) \wedge A_j(V)$ .
- $\hat{T}(\hat{V}, \hat{V}') \doteq T(V, V') \wedge \bigwedge_{j=0}^{m-1} l' = j \rightarrow R_j(V')$

1850 Notice that by construction the  $\hat{\mathcal{R}}$  are pairwise disjoint. We now show that  $H$  and  $\hat{H}$  admit the same paths with respect to the assignments over the common symbols  $V$  and that  $\hat{H}$  is in fact an  $E$ -component.

**Theorem 11.** *If  $H$  satisfies all hypotheses of Def. 3 then also  $\hat{H}$  does.*

*Proof.*

**I** By hypothesis  $I \rightarrow \bigvee_{j=0}^{m-1} R_j \wedge A_j$  holds and we need to show that

$$(I \wedge \bigwedge_{j=0}^{m-1} l = j \rightarrow (R_j \wedge A_j)) \rightarrow \bigvee_{j=0}^{m-1} R_j \wedge A_j \wedge l = j$$

1855 also holds. By hypothesis, for every state  $\mathbf{v}$  in  $I$  there must exist some  $j_0$  such that  $\mathbf{v} \models R_{j_0} \wedge A_{j_0}$ . By definition of  $l$ ,  $\bigvee_{j=0}^{m-1} l = j$  is valid, hence the left-hand-side of the implication  $l = j \rightarrow (R_j \wedge A_j)$  cannot be always false. Consider an assignment  $\hat{\mathbf{v}}$  over  $\hat{V}$  and let  $j_0$  such that  $\hat{\mathbf{v}} \models l = j_0$ . Then, if  $\hat{\mathbf{v}} \not\models R_{j_0} \wedge A_{j_0}$  our objective formula holds. Otherwise, 1860  $\hat{\mathbf{v}} \models R_{j_0} \wedge A_{j_0} \wedge l = j_0$ , hence  $\hat{\mathbf{v}} \models \bigvee_{j=0}^{m-1} R_j \wedge A_j \wedge l = j$ .

**II, III, IV** If  $\hat{H}$  admits a transition between two restricted regions  $\hat{R}_{j_0} \wedge A_{j_0}$  and  $\hat{R}_{j_1} \wedge A_{j_1}$  of one of the 3 kinds then, by construction of  $\hat{T}$ ,  $H$  must admit a transition of the same kind between its restricted regions  $R_{j_0} \wedge A_{j_0}$  and  $R_{j_1} \wedge A_{j_1}$ . Let  $t$  be the kind of the transition. All three hypotheses hold 1865 for  $H$ , hence every state in  $R_{j_0} \wedge A_{j_0}$  admits at least one successor in  $R_{j_1}$  via a  $t$ -transition, provided  $A_{j_1}$  holds. For every state  $\hat{\mathbf{v}}$  in  $\hat{R}_{j_0} \wedge A_{j_0}$ , let  $\mathbf{v}$  be its restriction to the symbols in  $V$ .  $\mathbf{v}$  is in  $R_{j_0} \wedge A_{j_0}$  and it admits a successor  $\mathbf{v}'$  via a  $t$ -transition. Then,  $\hat{\mathbf{v}}'$  defined by extending  $\mathbf{v}'$  with  $l' = j_1$ , is a  $t$ -successor for  $\hat{\mathbf{v}}$  in  $\hat{H}$ .

1870

□

**Theorem 12.** *The languages of  $H$  and  $\hat{H}$  admit the same set of paths projected over the symbols  $V$ .*

*Proof.* We prove the statement by induction on the length of the path. We first show that there is a one-to-one correspondence between the initial states and 1875 then show that a one-to-one correspondence exists also between the transitions.

• Every initial state  $\mathbf{v}_0$  of  $H$  must be such that  $I(\mathbf{v}_0)$  is true and, by Hyp. **I** there exists  $0 \leq j_0 < m$  such that  $R_{j_0}(\mathbf{v}_0) \wedge A_{j_0}(\mathbf{v}_0)$  also holds. We define an assignment  $\hat{\mathbf{v}}_0$  over  $\hat{V}$  by extending  $\mathbf{v}_0$  with the assignment  $l = j_0$ . By construction,  $\hat{I}(\hat{\mathbf{v}}_0)$  and  $\hat{R}_{j_0}(\hat{\mathbf{v}}_0) \wedge A_{j_0}(\hat{\mathbf{v}}_0)$  hold, hence  $\hat{\mathbf{v}}_0$  is an initial state for some path in  $\mathcal{L}(\hat{H})$ .

Viceversa, given an initial state  $\hat{\mathbf{v}}_0$  of  $\hat{H}$ , we define  $\mathbf{v}_0$  by restricting  $\hat{\mathbf{v}}_0$  to the assignments of the symbols in  $V$ . By construction,  $I(\mathbf{v}_0)$  is true and there exists  $0 \leq j_0 < m$  such that  $R_{j_0}(\mathbf{v}_0) \wedge A_{j_0}(\mathbf{v}_0)$  holds. Therefore,  $\mathbf{v}_0$  is an initial state for  $H$ .

• Consider a transition of  $H$  from assignment  $\mathbf{v}$  to  $\mathbf{v}'$ :  $\mathbf{v}, \mathbf{v}' \models R_j \wedge A_j \wedge T \wedge R_{j'} \wedge A_{j'}$  for some  $0 \leq j < m$  and  $0 \leq j' < m$ . By inductive hypothesis there is an assignment  $\hat{\mathbf{v}}$  for the symbols  $\hat{V}$  corresponding to  $\mathbf{v}$ . We show that  $\hat{H}$  admits a successor  $\hat{\mathbf{v}}'$  for  $\hat{\mathbf{v}}$  that corresponds to  $\mathbf{v}'$ . By hypothesis,  $\mathbf{v}' \models R_{j'} \wedge A_{j'}$ . We define  $\hat{\mathbf{v}}'$  by extending the assignment  $\mathbf{v}'$  with  $l = j'$ . Then,  $\hat{\mathbf{v}}'$  corresponds to  $\mathbf{v}'$  and  $\hat{\mathbf{v}}, \hat{\mathbf{v}}' \models \hat{R}_j \wedge A_j \wedge \hat{T} \wedge \hat{R}_{j'} \wedge \hat{A}_{j'}$ .

Viceversa, consider now a transition of  $\hat{H}$  from assignment  $\hat{\mathbf{v}}$  to  $\hat{\mathbf{v}}'$  and an assignment  $\mathbf{v} \doteq \hat{\mathbf{v}}_{\downarrow V}$  for the symbols  $V$  corresponding to  $\hat{\mathbf{v}}$ . By hypothesis,  $\hat{\mathbf{v}} \models \hat{R}_j \wedge A_j$  and  $\hat{\mathbf{v}}' \models \hat{R}_{j'} \wedge A_{j'}$  for some  $j$  and  $j'$ . By definition of  $\hat{R}_{j'}$ , the following holds:  $\hat{\mathbf{v}}' \models R_{j'}$ .  $\mathbf{v}' \doteq \hat{\mathbf{v}}'_{\downarrow V}$  is an assignment over the symbols  $V$  corresponding to  $\hat{\mathbf{v}}'$ . Since  $R_{j'}$  and  $A_{j'}$  do not depend on  $l$  and  $\hat{\mathbf{v}}' \models R_{j'} \wedge A_{j'}$ , then  $\mathbf{v}' \models R_{j'} \wedge A_{j'}$ . Hence,  $\mathbf{v}, \mathbf{v}' \models R_j \wedge A_j \wedge T \wedge R_{j'} \wedge A_{j'}$ . Therefore,  $\mathbf{v}'$  is a successor for  $\mathbf{v}$  in  $H$  corresponding to  $\hat{\mathbf{v}}'$ .

□

### Appendix B.3. Projection of E-components is closed

**Theorem 4.** *The projection  $H^\downarrow$  over indexes  $idxs$  of an E-component  $H$  over regions  $\mathcal{R}$ , assumptions  $\mathcal{A}$  and ranking functions  $\mathcal{W}$  is an E-component.*

*Proof.* We prove that hypotheses **I–IV** hold for  $H^\downarrow$ .

**I** holds by construction since every state  $\mathbf{v}$  such that  $I^\downarrow(\mathbf{v})$  must also satisfy  $\bigvee_{j \in idxs} (R_j(V) \wedge A_j(V))$  hence, by definition of  $\mathcal{R}^\downarrow$  and  $\mathcal{A}^\downarrow$ ,  $\mathbf{v}$  is also in some restricted region of  $H^\downarrow$ .

**II** For any  $j^\downarrow \in idxs$ , the region  $R_{j^\downarrow}^\downarrow$ , assumption  $A_{j^\downarrow}^\downarrow$  and ranking function  $\text{RF}_{j^\downarrow}^\downarrow$  are in both  $H^\downarrow$  and  $H$ . In all transitions such that  $R_j \wedge \text{RF}_j < \text{RF}_j \wedge R'_j$  holds for some  $j \in idxs$ ,  $T^\downarrow$  is equivalent to  $T$ . Therefore, since Hyp. **II** holds for  $H$ , it must also hold for  $H^\downarrow$ : if  $T$  admits a successor for every state in  $R_j \wedge A_j$  such that  $\text{RF}_j < \text{RF}_j \wedge R'_j$  hold, then so does  $T^\downarrow$ .

**III** By construction of  $T^\downarrow$  admits no stutter transition. Therefore, the left-hand-side of the entailment is false and Hyp. **III** holds.

1915 **IV** For any  $j^\downarrow, j^{\downarrow'} \in idxs$ , if they do not denote consecutive regions in the sequence,  $H^\downarrow$  does not admit any transition between them and Hyp. **IV** holds. Otherwise,  $j^\downarrow$  and  $j^{\downarrow'}$  are the consecutive indexes of the regions  $R_{j^\downarrow}^\downarrow$ ,  $R_{j^{\downarrow'}}^\downarrow$ , the assumptions  $A_{j^\downarrow}^\downarrow$ ,  $A_{j^{\downarrow'}}^\downarrow$ , and ranking functions  $\text{RF}_{j^\downarrow}^\downarrow$ . If  $H$  does not admit any progress transition between these regions, neither does  $H^\downarrow$  and Hyp. **IV** holds. Otherwise if  $H$  admits at least one transition between these regions, the following holds:

$$\exists V, V' : R_{j^\downarrow}^\downarrow \wedge A_{j^\downarrow}^\downarrow \wedge \text{RF}_{j^\downarrow}^\downarrow = \mathbf{0} \wedge T \wedge R_{j^{\downarrow'}}^\downarrow \wedge A_{j^{\downarrow'}}^\downarrow$$

1920 Every such  $V$  and  $V'$  satisfies  $T^\downarrow$ , hence it is also a transition for  $H^\downarrow$ . Therefore, since Hyp. **IV** holds for  $H$ , for every state in  $R_{j^\downarrow}^\downarrow \wedge A_{j^\downarrow}^\downarrow \wedge \text{RF}_{j^\downarrow}^\downarrow = \mathbf{0}$   $H$  admits a successor in  $R_{j^{\downarrow'}}^\downarrow \wedge A_{j^{\downarrow'}}^\downarrow$ . Every such transition is also admitted by  $H^\downarrow$  and Hyp. **IV** holds for  $H^\downarrow$ .

□

1925 *Appendix B.4. Composition of E-components is closed*

**Theorem 5.** *Given a set of E-components  $\{H^i\}_{i=0}^n$ , their composition  $H^c \doteq \bigotimes_{i=0}^n H^i = \langle V, I^c, T^c \rangle$  is an E-component with respect to regions  $\mathcal{R}^c$ , assumptions  $\mathcal{A}^c$  and ranking functions  $\mathcal{W}^c$ .*

1930 *Proof.* We need to prove that hypotheses **I–IV** hold for  $H^c$  of length  $m^c$ . In the following we write  $A_{j_i}^{i, \neq c}$  for  $\bigwedge_{h \notin \{0, \dots, n\}} A_{j_i}^{i, h} (V^h)$ .

**I** requires us to prove that the initial states of  $H^c$  are a subset of the union of the regions. This holds trivially from the definition of  $I^c$  since every state in this set must satisfy  $\bigvee_{j_c=0}^{m^c} R_{j_c}^c \wedge A_{j_c}^c$ .

**II** requires us to prove the following

$$\begin{aligned} \forall j : 0 \leq j < m^c \rightarrow \\ \exists V, V' : (R_j^c \wedge A_j^c \wedge T^c \wedge \text{RF}_j^{c'} < \text{RF}_j^c \wedge R_j^{c'} \wedge A_j^{c'}) \quad \models \\ \forall V \exists V^{c'} \forall V^{\neq c'} : R_j^c \wedge A_j^c \wedge \mathbf{0} < \text{RF}_j^c \wedge A_j^{c'} \rightarrow R_j^{c'} \wedge T^c \wedge \text{RF}_j^{c'} < \text{RF}_j^c \end{aligned}$$

$H^c \doteq \bigotimes_{i=0}^n H^i$  hence, by definition of  $\bigotimes$ ,  $R_j^c$  and  $A_j^c$  are the conjunction of some region and assumptions of  $\{H^i\}_{i=0}^n$ . Therefore, we can rewrite it as

follows:

$$\begin{aligned}
& \forall \{j_i\}_{i=0}^n : \left( \bigwedge_{i=0}^n 0 \leq j_i < m^i \right) \rightarrow \\
& \exists V, V' : \left( \bigwedge_{i=0}^n R_{j_i}^i \wedge \left( \bigwedge_{h=0, h \neq i}^n A_{j_i}^{i,h} \right) \wedge A_{j_i}^{i, \neq c} \wedge T^i \right) \wedge \text{compatible}_{\{H^i\}_{i=0}^n} \wedge \\
& \quad \text{indepRank}_{\{H^i\}_{i=0}^n} \wedge \text{RF}_j^{c'} < \text{RF}_j^c \wedge \left( \bigwedge_{i=0}^n R_{j_i}' \wedge \left( \bigwedge_{h=0, h \neq i}^n A_{j_i}^{i,h'} \right) \wedge A_{j_i}^{i, \neq c'} \right) \models \\
& \forall V \exists \{V^{i'}\}_{i=0}^n \forall V^{\neq c'} : \left( \left( \bigwedge_{i=0}^n R_{j_i}^i \wedge \left( \bigwedge_{h=0, h \neq i}^n A_{j_i}^{i,h} \right) \wedge A_{j_i}^{i, \neq c} \right) \wedge A_j^{c'} \wedge \mathbf{0} < \text{RF}_j^c \right) \rightarrow \\
& \quad \left( \left( \bigwedge_{i=0}^n R_{j_i}' \wedge \left( \bigwedge_{h=0, h \neq i}^n A_{j_i}^{i,h'} \right) \wedge T^i \right) \wedge \text{compatible}_{\{H^i\}_{i=0}^n} \wedge \text{indepRank}_{\{H^i\}_{i=0}^n} \wedge \right. \\
& \quad \left. \text{RF}_j^{c'} < \text{RF}_j^c \right)
\end{aligned}$$

For any  $0 \leq i \leq n$   $A_j^i(V^{\neq c}) \wedge \bigwedge_{h=0, h \neq i}^n A_{j_i}^{i,h}(V^h)$  is equivalent to  $A_j^i(V^{\neq i})$ . Therefore, our objective formula can be rewritten as:

$$\begin{aligned}
& \forall \{j_i\}_{i=0}^n : \left( \bigwedge_{i=0}^n 0 \leq j_i < m^i \right) \rightarrow \\
& \exists V, V' : \left( \bigwedge_{i=0}^n R_{j_i}^i \wedge A_{j_i}^i \wedge T^i \wedge R_{j_i}' \wedge A_{j_i}' \right) \wedge \text{compatible}_{\{H^i\}_{i=0}^n} \wedge \\
& \quad \text{indepRank}_{\{H^i\}_{i=0}^n} \wedge \text{RF}_j^{c'} < \text{RF}_j^c \models \\
& \forall V \exists \{V^{i'}\}_{i=0}^n \forall V^{\neq c'} : \left( \left( \bigwedge_{i=0}^n R_{j_i}^i \wedge A_{j_i}^i \right) \wedge A_j^{c'} \wedge \mathbf{0} < \text{RF}_j^c \right) \rightarrow \left( \left( \bigwedge_{i=0}^n T^i \wedge R_{j_i}' \wedge \right. \right. \\
& \quad \left. \left. \bigwedge_{h=0, h \neq i}^n A_{j_i}^{i,h'} \right) \wedge \text{compatible}_{\{H^i\}_{i=0}^n} \wedge \text{indepRank}_{\{H^i\}_{i=0}^n} \wedge \text{RF}_j^{c'} < \text{RF}_j^c \right)
\end{aligned}$$

If  $\text{indepRank}_{\{H^i\}_{i=0}^n}$  [resp.  $\text{compatible}_{\{H^i\}_{i=0}^n}$ ] does not hold in the left-hand-side of the entailment the formula is trivially true. By definition of  $\text{indepRank}_{\{H^i\}_{i=0}^n}$  [resp.  $\text{compatible}_{\{H^i\}_{i=0}^n}$ ], if it holds in the left-hand-side of the entailment it must also hold on the right-hand-side, since on both sides  $V$  and  $V'$  belong to the same regions. Therefore,  $\text{compatible}_{\{H^i\}_{i=0}^n}$  must hold and when both sides of the implication on the right-hand-side of the entailment hold,  $\bigwedge_{i=0}^n \bigwedge_{h=0, h \neq i}^n A_{j_i}^{i,h}(V^{h'})$  must

be true. We can further simplify our objective formula as follows:

$$\begin{aligned} \forall \{j_i\}_{i=0}^n : \left( \bigwedge_{i=0}^n 0 \leq j_i < m^i \right) \rightarrow \exists V, V' : \left( \bigwedge_{i=0}^n R_{j_i}^i \wedge A_{j_i}^i \wedge T^i \wedge R_{j_i}^{i'} \wedge A_{j_i}^{i'} \right) \wedge \\ \text{compatible}_{\{H^i\}_{i=0}^n} \wedge \text{indepRank}_{\{H^i\}_{i=0}^n} \wedge \text{RF}_{j'}^{c'} < \text{RF}_j^c \quad \models \forall V \exists \{V^{i'}\}_{i=0}^n \forall V \neq c' : \\ \left( \left( \bigwedge_{i=0}^n R_{j_i}^i \wedge A_{j_i}^i \right) \wedge A_j^{c'} \wedge \mathbf{0} < \text{RF}_j^c \right) \rightarrow \left( \left( \bigwedge_{i=0}^n T^i \wedge R_{j_i}^{i'} \right) \wedge \text{RF}_{j'}^{c'} < \text{RF}_j^c \right) \end{aligned}$$

If the left-hand-side of the entailment is false, then the formula is trivially true. Therefore, assume that there exists a transition performing a self-loop on the restricted region  $R_j^c \wedge A_j^c$  with *independent ranks* in which the sum of the ranking function decreases. Under this assumption, we need to prove the following for any  $j \doteq \langle j_0, \dots, j_n \rangle$  satisfying the above:

$$\begin{aligned} \forall V \exists \{V^{i'}\}_{i=0}^n \forall V \neq c' : \\ \left( \left( \bigwedge_{i=0}^n R_{j_i}^i \wedge A_{j_i}^i \right) \wedge A_j^{c'} \wedge \mathbf{0} < \text{RF}_j^c(V) \right) \rightarrow \left( \left( \bigwedge_{i=0}^n T^i \wedge R_{j_i}^{i'} \right) \wedge \text{RF}_{j'}^{c'} < \text{RF}_j^c \right) \end{aligned}$$

Since  $\text{indepRank}_{\{H^i\}_{i=0}^n}$  holds for indexes  $\langle j_0, \dots, j_n \rangle$  we have:

$$\begin{aligned} \bigwedge_{i=0}^n (\forall V : \left( \bigwedge_{h=0}^n R_{j_h}^h \wedge A_{j_h}^h \right) \rightarrow \text{RF}_{j_i}^i = \mathbf{0}) \vee \\ \exists V, V' : \left( \bigwedge_{h=0}^n R_{j_h}^h \wedge A_{j_h}^h \wedge T^h \wedge R_{j_h}^{h'} \wedge A_{j_h}^{h'} \right) \wedge \\ \text{RF}_{j_i}^{i'} < \text{RF}_{j_i}^i \wedge \left( \bigwedge_{k=0, k \neq h}^n \text{RF}_{j_i}^k = \text{RF}_{j_i}^k \right) \wedge \text{compatible}_{\{H^i\}_{i=0}^n} \end{aligned}$$

In addition, since there exists a transition in the restricted regions such that  $\text{RF}_j^c$  decreases, there must be some  $0 \leq i_r \leq n$  such that  $\exists V : \left( \bigwedge_{h=0}^n R_{j_h}^h(V) \wedge A_{j_h}^h(V \neq h) \right) \wedge \mathbf{0} < \text{RF}_{j_{i_r}}^{i_r}(V)$ . Then, there exist compatible transitions in which its ranking function decreases  $\text{RF}_{j_r}^{i_r}(V') < \text{RF}_{j_r}^{i_r}(V)$ , while all other ranking function remain constant  $\bigwedge_{i=0, i \neq i_r}^n \text{RF}_{j_i}^i(V') = \text{RF}_{j_i}^i(V)$ . Hyp. **II** holds for  $H^{i_r}$ :

$$\begin{aligned} \forall j_r : 0 \leq j_r < m^{i_r} \rightarrow \exists V, V' : \left( R_{j_r}^{i_r} \wedge A_{j_r}^{i_r} \wedge T^{i_r} \wedge \text{RF}_{j_r}^{i_r'} < \text{RF}_{j_r}^{i_r} \wedge R_{j_r}^{i_r'} \wedge A_{j_r}^{i_r'} \right) \models \\ \forall V \exists V^{i_r'} \forall V \neq i_r' : R_{j_r}^{i_r} \wedge A_{j_r}^{i_r} \wedge \mathbf{0} < \text{RF}_{j_r}^{i_r} \wedge A_{j_r}^{i_r'} \rightarrow R_{j_r}^{i_r'} \wedge T^{i_r} \wedge \text{RF}_{j_r}^{i_r'} < \text{RF}_{j_r}^{i_r} \end{aligned}$$

and Hyp. **III** holds for all  $\{H^i\}_{i=0, i \neq i_r}^n$ :

$$\begin{aligned} \forall j_i : 0 \leq j_i < m^i \rightarrow \exists V, V' : \left( R_{j_i}^i \wedge A_{j_i}^i \wedge T^i \wedge \text{RF}_{j_i}^{i'} = \text{RF}_{j_i}^i \wedge R_{j_i}^{i'} \wedge A_{j_i}^{i'} \right) \models \\ \forall V \exists V^{i'} \forall V \neq i' : R_{j_i}^i \wedge A_{j_i}^i \wedge A_{j_i}^{i'} \rightarrow R_{j_i}^{i'} \wedge T^i \wedge \text{RF}_{j_i}^{i'} = \text{RF}_{j_i}^i \end{aligned}$$

If there is no transition in the intersection of the restricted regions such that  $\text{RF}_j^c$  decreases or they are not compatible, the objective formula trivially holds because the left-hand-side of the entailment is false. Then, the conjunction of the hypotheses for the  $\{H^i\}_{i=0}^n$  implies:

$$\begin{aligned} & \forall \{j_i\}_{i=0}^n : \left( \bigwedge_{i=0}^n 0 \leq j_i < m^i \right) \rightarrow \\ & \exists V, V' : \left( \bigwedge_{i=0}^n (R_{j_i}^i \wedge A_{j_i}^i \wedge T^i \wedge R_{j_i}^{i'} \wedge A_{j_i}^{i'}) \wedge \text{RF}_{j_r}^{i_r'} < \text{RF}_{j_r}^{i_r} \wedge \bigwedge_{i=0, i \neq r}^n \text{RF}_{j_i}^{i'} = \text{RF}_{j_i}^i \right) \models \\ & \forall V \exists V^{i_r'} \forall V^{\neq i_r'} : R_{j_r}^{i_r} \wedge A_{j_r}^{i_r} \wedge \mathbf{0} < \text{RF}_{j_r}^{i_r} \wedge A_{j_r}^{i_r'} \rightarrow R_{j_r}^{i_r'} \wedge T^{i_r} \wedge \text{RF}_{j_r}^{i_r'} < \text{RF}_{j_r}^{i_r} \wedge \\ & \bigwedge_{i=0, i \neq r}^n \forall V \exists V^{i'} \forall V^{\neq i'} : R_{j_i}^i \wedge A_{j_i}^i \wedge A_{j_i}^{i'} \rightarrow R_{j_i}^{i'} \wedge T^i \wedge \text{RF}_{j_i}^{i'} = \text{RF}_{j_i}^i \end{aligned}$$

The left hand side of the entailment must hold, otherwise our objective formula is trivially true.

$$\begin{aligned} & \forall V \exists V^{i_r'} \forall V^{\neq i_r'} : R_{j_r}^{i_r} \wedge A_{j_r}^{i_r} \wedge \mathbf{0} < \text{RF}_{j_r}^{i_r} \wedge A_{j_r}^{i_r'} \rightarrow R_{j_r}^{i_r'} \wedge T^{i_r} \wedge \text{RF}_{j_r}^{i_r'} < \text{RF}_{j_r}^{i_r} \wedge \\ & \bigwedge_{i=0, i \neq r}^n \forall V \exists V^{i'} \forall V^{\neq i'} : R_{j_i}^i \wedge A_{j_i}^i \wedge A_{j_i}^{i'} \rightarrow R_{j_i}^{i'} \wedge T^i \wedge \text{RF}_{j_i}^{i'} = \text{RF}_{j_i}^i \end{aligned}$$

If a  $\forall V \exists V^{i'} \forall V^{\neq i'}$  quantified implication holds, then for every assignment to the symbols  $V$  such that  $R_{j_i}^i(V)$ ,  $A_{j_i}^i(V^{\neq i})$  and, if  $i = i_r$ , also  $\mathbf{0} < \text{RF}_{j_r}^{i_r}(V)$  hold, there exists an assignment to  $V^{i'}$  satisfying the assumptions of all other  $E$ -components  $\bigwedge_{s=0, s \neq i}^n A_{j_s}^{s, i}(V^{i'})$ , for all assignments to the  $V^{\neq i'}$ . Therefore, we can write the following:

$$\begin{aligned} & \forall V \exists \{V^{i'}\}_{i=0}^n \forall V^{\neq c'} : (R_{j_r}^{i_r} \wedge A_{j_r}^{i_r} \wedge \mathbf{0} < \text{RF}_{j_r}^{i_r} \wedge A_{j_r}^{i_r, \neq c'} \rightarrow R_{j_r}^{i_r'} \wedge T^{i_r} \wedge \text{RF}_{j_r}^{i_r'} < \text{RF}_{j_r}^{i_r}) \wedge \\ & \bigwedge_{i=0, i \neq r}^n R_{j_i}^i \wedge A_{j_i}^i \wedge A_{j_i}^{i, \neq c'} \rightarrow R_{j_i}^{i'} \wedge T^i \wedge \text{RF}_{j_i}^{i'} = \text{RF}_{j_i}^i \end{aligned}$$

$\mathbf{0} < \text{RF}_{j_r}^{i_r}(V)$  implies  $\mathbf{0} < \text{RF}_j^c(V)$  and, since  $(a \rightarrow b) \wedge (c \rightarrow d)$  implies  $(a \wedge c) \rightarrow (b \wedge d)$ , the formula above implies:

$$\begin{aligned} & \forall V \exists \{V^{i'}\}_{i=0}^n \forall V^{\neq c'} : (\mathbf{0} < \text{RF}_j^c \wedge \left( \bigwedge_{i=0}^n R_{j_i}^i \wedge A_{j_i}^i \wedge A_{j_i}^{i, \neq c'} \right)) \rightarrow \\ & \text{RF}_{j_r}^{i_r'} < \text{RF}_{j_r}^{i_r} \wedge \left( \bigwedge_{i=0, i \neq i_r}^n \text{RF}_{j_i}^{i'} = \text{RF}_{j_i}^i \right) \wedge \bigwedge_{i=0}^n R_{j_i}^{i'} \wedge T^i \end{aligned}$$

The formula  $\text{RF}_{j_r}^{i_r'}(V') < \text{RF}_{j_r}^{i_r}(V) \wedge \left( \bigwedge_{i=0, i \neq i_r}^n \text{RF}_{j_i}^i(V') = \text{RF}_{j_i}^i(V) \right)$  implies  $\text{RF}_j^c(V') < \text{RF}_j^c(V)$  and  $\bigwedge_{i=0}^n A_{j_i}^i(V^{\neq c})$  is equivalent to  $A_j^c(V^{\neq c})$

Therefore, we obtain the implied statement:

$$\forall V \exists \{V^{i'}\}_{i=0}^n \forall V^{\neq c'} : \\ ((\bigwedge_{i=0}^n R_{j_i}^i \wedge A_{j_i}^i) \wedge A_j^{c'} \wedge \mathbf{0} < \mathbf{RF}_j^c) \rightarrow ((\bigwedge_{i=0}^n T^i \wedge R_{j_i}^{i'}) \wedge \mathbf{RF}_j^{c'} < \mathbf{RF}_j^c)$$

which is exactly the formula we wanted to prove.

**III** requires us to prove the following

$$\forall j : 0 \leq j < m^c \rightarrow \\ \exists V, V' : (R_j^c \wedge A_j^c \wedge T^c \wedge \mathbf{RF}_j^{c'} = \mathbf{RF}_j^c \wedge R_{j_i}^{c'} \wedge A_j^{c'}) \models \\ \forall V \exists V^{c'} \forall V^{\neq c'} : R_j^c \wedge A_j^c \wedge A_j^{c'} \rightarrow R_{j_i}^{c'} \wedge T^c \wedge \mathbf{RF}_j^{c'} = \mathbf{RF}_j^c$$

By definition of  $\otimes$  and since  $H^c \doteq \bigotimes_{i=0}^n H^i$  we can rewrite it as:

$$\forall \{j_i\}_{i=0}^n : (\bigwedge_{i=0}^n 0 \leq j_i < m^i) \rightarrow \\ \exists V, V' : (\bigwedge_{i=0}^n R_{j_i}^i \wedge (\bigwedge_{h=0, h \neq i}^n A_{j_i}^{i,h}) \wedge A_{j_i}^{i, \neq c} \wedge T^i) \wedge \text{compatible}_{\{H^i\}_{i=0}^n} \wedge \\ \text{indepRank}_{\{H^i\}_{i=0}^n} \wedge \mathbf{RF}_j^{c'} = \mathbf{RF}_j^c \wedge (\bigwedge_{i=0}^n R_{j_i}^{i'} \wedge (\bigwedge_{h=0, h \neq i}^n A_{j_i}^{i,h'}) \wedge A_{j_i}^{i, \neq c'}) \models \\ \forall V \exists \{V^{i'}\}_{i=0}^n \forall V^{\neq c'} : ((\bigwedge_{i=0}^n R_{j_i}^i \wedge (\bigwedge_{h=0, h \neq i}^n A_{j_i}^{i,h}) \wedge A_{j_i}^{i, \neq c}) \wedge A_j^{c'}) \rightarrow ((\bigwedge_{i=0}^n R_{j_i}^{i'} \wedge \\ (\bigwedge_{h=0, h \neq i}^n A_{j_i}^{i,h'}) \wedge T^i) \wedge \text{compatible}_{\{H^i\}_{i=0}^n} \wedge \text{indepRank}_{\{H^i\}_{i=0}^n} \wedge \mathbf{RF}_j^{c'} = \mathbf{RF}_j^c)$$

On both sides of the entailment  $\mathbf{RF}_j^c(V') = \mathbf{RF}_j^c(V)$  holds, hence  $\text{indepRank}_{\{H^i\}_{i=0}^n}$  is trivially true: the left-hand-side of the implication in its definition is false. In addition, for any  $0 \leq i \leq n$   $A_{j_i}^i(V^{\neq c}) \wedge \bigwedge_{h=0, h \neq i}^n A_{j_i}^{i,h}(V^h)$  is equivalent to  $A_{j_i}^i(V^{\neq i})$ . Therefore, our objective formula can be rewritten as:

$$\forall \{j_i\}_{i=0}^n : (\bigwedge_{i=0}^n 0 \leq j_i < m^i) \rightarrow \\ \exists V, V' : (\bigwedge_{i=0}^n R_{j_i}^i \wedge A_{j_i}^i \wedge T^i \wedge R_{j_i}^{i'} \wedge A_{j_i}^{i'}) \wedge \mathbf{RF}_j^{c'} = \mathbf{RF}_j^c \wedge \text{compatible}_{\{H^i\}_{i=0}^n} \models \\ \forall V \exists \{V^{i'}\}_{i=0}^n \forall V^{\neq c'} : ((\bigwedge_{i=0}^n R_{j_i}^i \wedge A_{j_i}^i) \wedge A_j^{c'}) \rightarrow ((\bigwedge_{i=0}^n T^i \wedge R_{j_i}^{i'} \wedge \bigwedge_{h=0, h \neq i}^n A_{j_i}^{i,h'}) \wedge \\ \mathbf{RF}_j^{c'} = \mathbf{RF}_j^c \wedge \text{compatible}_{\{H^i\}_{i=0}^n})$$

If  $compatible_{\{H^i\}_{i=0}^n}(V, V')$  does not hold, then the left-hand-side of the entailment is false, hence the entailment is true. Otherwise,  $compatible_{\{H^i\}_{i=0}^n}$  holds and since it holds on the left-hand-side of the entailment, it must also hold on the right-hand-side; when both sides of the implication on the right-hand-side of the entailment hold,  $\bigwedge_{i=0}^n \bigwedge_{h=0, h \neq i}^n A_{j_i}^{i,h}(V^{h'})$  must be true since  $compatible_{\{H^i\}_{i=0}^n}$  holds. We can further simplify our objective formula as follows:

$$\begin{aligned} \forall \{j_i\}_{i=0}^n : \left( \bigwedge_{i=0}^n 0 \leq j_i < m^i \right) \rightarrow \\ \exists V, V' : \left( \bigwedge_{i=0}^n R_{j_i}^i \wedge A_{j_i}^i \wedge T^i \wedge R_{j_i}^{i'} \wedge A_{j_i}^{i'} \right) \wedge \text{RF}_j^{c'} = \text{RF}_j^c \wedge compatible_{\{H^i\}_{i=0}^n} \quad \models \\ \forall V \exists \{V^{i'}\}_{i=0}^n \forall V^{\neq c'} : \left( \left( \bigwedge_{i=0}^n R_{j_i}^i \wedge A_{j_i}^i \right) \wedge A_j^{c'} \right) \rightarrow \left( \left( \bigwedge_{i=0}^n T^i \wedge R_{j_i}^{i'} \right) \wedge \text{RF}_j^{c'} = \text{RF}_j^c \right) \end{aligned}$$

If the left-hand-side of the entailment is false, then the formula is trivially true. Therefore, assume that there exists a transition performing a self-loop on the restricted region  $R_j^c \wedge A_j^c$  in which the ranking function remains constant. Under this assumption, we need to prove the following for any  $j \doteq \langle j_0, \dots, j_n \rangle$  satisfying the above:

$$\forall V \exists \{V^{i'}\}_{i=0}^n \forall V^{\neq c'} : \left( \left( \bigwedge_{i=0}^n R_{j_i}^i \wedge A_{j_i}^i \right) \wedge A_j^{c'} \right) \rightarrow \left( \text{RF}_j^{c'} = \text{RF}_j^c \wedge \bigwedge_{i=0}^n T^i \wedge R_{j_i}^{i'} \right)$$

Hyp. **III** holds for all  $E$ -components  $\{H^i\}_{i=0}^n$ :

$$\begin{aligned} \forall j_i : 0 \leq j_i < m^i \rightarrow \\ \exists V, V' : \left( R_{j_i}^i \wedge A_{j_i}^i \wedge T^i \wedge \text{RF}_{j_i}^{i'} = \text{RF}_{j_i}^i \wedge R_{j_i}^{i'} \wedge A_{j_i}^{i'} \right) \quad \models \\ \forall V \exists V^{i'} \forall V^{\neq i'} : R_{j_i}^i \wedge A_{j_i}^i \wedge A_{j_i}^{i'} \rightarrow R_{j_i}^{i'} \wedge T^i \wedge \text{RF}_{j_i}^{i'} = \text{RF}_{j_i}^i \end{aligned}$$

By assumption there exists a transition in the intersection of their restricted regions such that  $\text{RF}_j^{c'}(V') = \text{RF}_j^c(V)$ , and hence  $\text{RF}_{j_i}^{i'}(V') = \text{RF}_{j_i}^i(V)$  for all  $i$ . Therefore, their conjunction implies:

$$\bigwedge_{i=0}^n \forall V \exists V^{i'} \forall V^{\neq i'} : R_{j_i}^i \wedge A_{j_i}^i \wedge A_{j_i}^{i'} \rightarrow R_{j_i}^{i'} \wedge T^i \wedge \text{RF}_{j_i}^{i'} = \text{RF}_{j_i}^i$$

If a  $\forall V \exists V^{i'} \forall V^{\neq i'}$  quantified implication holds then for every assignment to the symbols  $V$  such that  $R_{j_i}^i(V) \wedge A_{j_i}^i(V^{\neq i}) \wedge A_{j_i}^i(V^{\neq i'})$  holds, there exists an assignment to the  $V^{i'}$  satisfying the assumptions of all other  $E$ -components  $\bigwedge_{s=0, s \neq i}^n A_{j_s}^{s,i}(V^{i'})$ , for all assignments to the  $V^{\neq i'}$ . Therefore, we can write the following:

$$\forall V \exists \{V^{i'}\}_{i=0}^n \forall V^{\neq c'} : \bigwedge_{i=0}^n \left( R_{j_i}^i \wedge A_{j_i}^i \wedge A_{j_i}^{i, \neq c'} \right) \rightarrow \left( R_{j_i}^{i'} \wedge T^i \wedge \text{RF}_{j_i}^{i'} = \text{RF}_{j_i}^i \right)$$

Since  $(a \rightarrow b) \wedge (c \rightarrow d)$  implies  $(a \wedge c) \rightarrow (b \wedge d)$  and  $\bigwedge_{i=0}^n \text{RF}_{j_i}^i(V') = \text{RF}_{j_i}^i(V)$  implies  $\text{RF}_j^c(V') = \text{RF}_j^c(V)$ , the formula above implies:

$$\forall V \exists \{V^{i'}\}_{i=0}^n \forall V^{\neq c'} : \left( \bigwedge_{i=0}^n R_{j_i}^i \wedge A_{j_i}^i \right) \wedge A_j^{c'} \rightarrow (\text{RF}_j^{c'} = \text{RF}_j^c \wedge \bigwedge_{i=0}^n T^i \wedge R_{j_i}^{i'})$$

1935

which is exactly the formula we wanted to prove.

**IV** requires us to prove the following

$$\begin{aligned} \forall j, j' : 0 \leq j < m^c \wedge 0 \leq j' < m^c &\rightarrow \\ \exists V, V' : (R_j^c \wedge A_j^c \wedge T^c \wedge \text{RF}_j^c = \mathbf{0} \wedge R_{j'}^{c'} \wedge A_{j'}^{c'}) &\models \\ \forall V \exists V^c \forall V^{\neq c'} : R_j^c \wedge A_j^c \wedge \text{RF}_j^c = \mathbf{0} \wedge A_{j'}^{c'} &\rightarrow R_{j'}^{c'} \wedge T^c \end{aligned}$$

By definition of  $\otimes$  and since  $H^c \doteq \bigotimes_{i=0}^n H^i$  we can rewrite it as:

$$\begin{aligned} \forall \{j_i\}_{i=0}^n, \{j'_i\}_{i=0}^n : \left( \bigwedge_{i=0}^n 0 \leq j_i < m^i \wedge 0 \leq j'_i < m^i \right) &\rightarrow \\ \exists V, V' : \left( \bigwedge_{i=0}^n R_{j_i}^i \wedge \left( \bigwedge_{h=0, h \neq i}^n A_{j_i}^{i,h} \right) \wedge A_{j_i}^{i, \neq c} \wedge T^i \right) \wedge \text{compatible}_{\{H^i\}_{i=0}^n} \wedge & \\ \text{indepRank}_{\{H^i\}_{i=0}^n} \wedge \text{RF}_j^c = \mathbf{0} \wedge \left( \bigwedge_{i=0}^n R_{j'_i}^{i'} \wedge \left( \bigwedge_{h=0, h \neq i}^n A_{j'_i}^{i,h'} \right) \wedge A_{j'_i}^{i, \neq c'} \right) &\models \\ \forall V \exists \{V^{i'}\}_{i=0}^n \forall V^{\neq c'} : \left( \left( \bigwedge_{i=0}^n R_{j_i}^i \wedge \left( \bigwedge_{h=0, h \neq i}^n A_{j_i}^{i,h} \right) \wedge A_{j_i}^{i, \neq c} \right) \wedge \text{RF}_j^c = \mathbf{0} \wedge A_{j'}^{c'} \right) &\rightarrow \\ \left( \left( \bigwedge_{i=0}^n R_{j'_i}^{i'} \wedge T^i \wedge \bigwedge_{h=0, h \neq i}^n A_{j'_i}^{i,h'} \right) \wedge \text{compatible}_{\{H^i\}_{i=0}^n} \wedge \text{indepRank}_{\{H^i\}_{i=0}^n} \right) & \end{aligned}$$

If  $j \neq j'$ ,  $\text{indepRank}_{\{H^i\}_{i=0}^n}$  trivially holds, since the left-hand-side of the implication in its definition is false. Otherwise, if  $j = j'$ ,  $\text{RF}_j^c(V) = \mathbf{0}$  contradicts  $\text{RF}_j^c(V') < \text{RF}_j^c(V)$  and again  $\text{indepRank}_{\{H^i\}_{i=0}^n}$  trivially holds because the left-hand-side of the implication in its definition is false. In addition, for any  $0 \leq i \leq n$   $A_j^i(V^{\neq c}) \wedge \bigwedge_{h=0, h \neq i}^n A_{j_i}^{i,h}(V^h)$  is equivalent

to  $A_j^i(V^{\neq i})$ . Therefore, our objective formula can be rewritten as:

$$\begin{aligned}
& \forall \{j_i\}_{i=0}^n, \{j'_i\}_{i=0}^n : \left( \bigwedge_{i=0}^n 0 \leq j_i < m^i \wedge 0 \leq j'_i < m^i \right) \rightarrow \\
& \exists V, V' : \left( \bigwedge_{i=0}^n R_{j_i}^i \wedge A_{j_i}^i \wedge T^i \wedge R_{j'_i}^{i'} \wedge A_{j'_i}^{i'} \right) \wedge \text{compatible}_{\{H^i\}_{i=0}^n} \wedge \text{RF}_j^c = \mathbf{0} \quad \models \\
& \forall V \exists \{V^{i'}\}_{i=0}^n \forall V^{\neq c'} : \left( \left( \bigwedge_{i=0}^n R_{j_i}^i \wedge A_{j_i}^i \right) \wedge \text{RF}_j^c = \mathbf{0} \wedge A_{j'_i}^{c'} \right) \rightarrow \\
& \left( \left( \bigwedge_{i=0}^n T^i \wedge R_{j'_i}^{i'} \wedge \bigwedge_{h=0, h \neq i}^n A_{j'_i}^{i, h'} \right) \wedge \text{compatible}_{\{H^i\}_{i=0}^n} \right)
\end{aligned}$$

If  $\text{compatible}_{\{H^i\}_{i=0}^n}(V, V')$  does not hold, then the left-hand-side of the entailment is false, hence the entailment is true. Otherwise  $\text{compatible}_{\{H^i\}_{i=0}^n}$  holds and since it holds on the left-hand-side of the entailment, it must also hold on the right-hand-side; when both sides of the implication on the right-hand-side of the entailment hold,  $\bigwedge_{i=0}^n \bigwedge_{h=0, h \neq i}^n A_{j'_i}^{i, h'}(V^{h'})$  must be true since  $\text{compatible}_{\{H^i\}_{i=0}^n}$  holds. We can further simplify our objective formula as follows:

$$\begin{aligned}
& \forall \{j_i\}_{i=0}^n, \{j'_i\}_{i=0}^n : \left( \bigwedge_{i=0}^n 0 \leq j_i < m^i \wedge 0 \leq j'_i < m^i \right) \rightarrow \\
& \exists V, V' : \left( \bigwedge_{i=0}^n R_{j_i}^i \wedge A_{j_i}^i \wedge T^i \wedge R_{j'_i}^{i'} \wedge A_{j'_i}^{i'} \right) \wedge \text{compatible}_{\{H^i\}_{i=0}^n} \wedge \text{RF}_j^c = \mathbf{0} \quad \models \\
& \forall V \exists \{V^{i'}\}_{i=0}^n \forall V^{\neq c'} : (\text{RF}_j^c = \mathbf{0} \wedge \bigwedge_{i=0}^n R_{j_i}^i \wedge A_{j_i}^i \wedge A_{j'_i}^{i, \neq c'}) \rightarrow \left( \bigwedge_{i=0}^n T^i \wedge R_{j'_i}^{i'} \right)
\end{aligned}$$

If the left-hand-side of the entailment is false, then the formula is trivially true. Therefore, assume that there exists a transition from a state in  $R_j^c \wedge A_j^c \wedge \text{RF}_j^c = \mathbf{0}$  to  $R_{j'}^c \wedge A_{j'}^c$ . Under this assumption, we need to prove the following for any  $j = \langle j_0, \dots, j_n \rangle$  satisfying the above:

$$\forall V \exists \{V^{i'}\}_{i=0}^n \forall V^{\neq c'} : (\text{RF}_j^c = \mathbf{0} \wedge \bigwedge_{i=0}^n R_{j_i}^i \wedge A_{j_i}^i \wedge A_{j'_i}^{i, \neq c'}) \rightarrow \left( \bigwedge_{i=0}^n T^i \wedge R_{j'_i}^{i'} \right)$$

Each  $E$ -component  $H^i$  allows for a transition from its restricted region with index  $j_i$  to the one with index  $j'_i$ . In this transition since  $\text{RF}_j^c(V) = \mathbf{0}$ , then  $\text{RF}_{j_i}^i(V) = \mathbf{0}$  holds in the source state. The following holds since Hyp. **IV** holds for all  $\{H^i\}_{i=0}^n$ .

$$\begin{aligned}
& \exists V, V' : (R_{j_i}^i \wedge A_{j_i}^i \wedge T^i \wedge \text{RF}_{j_i}^i = \mathbf{0} \wedge R_{j'_i}^{i'} \wedge A_{j'_i}^{i'}) \quad \models \\
& \forall V \exists V^{i'} \forall V^{\neq i'} : (R_{j_i}^i \wedge A_{j_i}^i \wedge \text{RF}_{j_i}^i = \mathbf{0} \wedge A_{j'_i}^{i'}) \rightarrow R_{j'_i}^{i'} \wedge T^i
\end{aligned}$$

If a  $\forall V \exists V^{i'} \forall V^{\neq i'}$  quantified implication holds then for every assignment to the symbols  $V$  such that  $R_{j_i}^i(V) \wedge A_{j_i}^i(V^{\neq i}) \wedge A_{j_i}^{i'}(V^{\neq i'})$  holds, there exists an assignment to the  $V^{i'}$  satisfying the assumptions of all other  $E$ -components  $\bigwedge_{s=0, s \neq i}^n A_{j_s}^{s, i}(V^{i'})$ , for all assignments to the  $V^{\neq i'}$ . Therefore, we can write the following:

$$\forall V \exists \{V^{i'}\}_{i=0}^n \forall V^{\neq i'} : \bigwedge_{i=0}^n ((R_{j_i}^i \wedge A_{j_i}^i \wedge \text{RF}_{j_i}^i = \mathbf{0} \wedge A_{j_i}^{i, \neq i'}) \rightarrow (R_{j_i}^{i'} \wedge T^{i'}))$$

Since  $(a \rightarrow b) \wedge (c \rightarrow d)$  implies  $(a \wedge c) \rightarrow (b \wedge d)$  and  $\bigwedge_{i=0}^n \text{RF}_{j_i}^i(V) = \mathbf{0}$  implies  $\text{RF}_j^c(V) = \mathbf{0}$ , we can write the following implied statement:

$$\forall V \exists \{V^{i'}\}_{i=0}^n \forall V^{\neq i'} : (\text{RF}_j^c = \mathbf{0} \wedge \bigwedge_{i=0}^n R_{j_i}^i \wedge A_{j_i}^i \wedge A_{j_i}^{i, \neq i'}) \rightarrow (\bigwedge_{i=0}^n T^i \wedge R_{j_i}^{i'})$$

which is exactly the formula we wanted to prove.  $\square$

#### Appendix B.5. E-CHC encoding of funnel-loop search is sound

**Theorem 7.** *Given a fair transition system  $M \doteq \langle V, I^M, T^M, F^M \rangle$  and an interpretation for the queries  $R, T$  and  $\text{Rank}$  satisfying all Eqs. (A.1)–(A.7). Then there exist a funnel-loop for  $M$ .*

*Proof.* We first show that,  $R(c, V)$  and  $T(V, V')$  correspond to a funnel and then show that such funnel corresponds to a funnel-loop of length one. We define a funnel  $fnl \doteq \langle S(V), T_{fnl}(V, V'), D(V), \text{RF}(V) \rangle$ , where (i)  $S(V) \doteq \exists c : R(c, V)$ , (iv)  $T_{fnl}(V, V') \doteq T(V, V') \wedge (D(V') \leftrightarrow \text{RF}(V) = \mathbf{0})$ , (iii)  $D(V) \doteq \exists c : c \wedge R(c, V)$  and (iii)  $\text{RF}(V)$  is a ranking function witnessing the well-foundedness of relation  $\text{Rank}(V, V')$ .  $\text{RF}$  is such that  $\text{RF}(V) = 0$  for all  $V$  such that there exist no  $V'$  making  $\neg c \wedge R(c, V) \wedge T(V, V') \wedge \wedge c' R(c', V')$  hold:

$$\forall c, V, c' : \neg(\exists V' : \neg c \wedge R(c, V) \wedge T(V, V') \wedge c' \wedge R(c', V')) \rightarrow \text{RF}_i(V) = 0$$

and in all other cases  $(R(c, V) \wedge T(V, V') \wedge R(c, V'))$  holds for all  $V, V'$  the following must hold:

$$\forall V, V' : (\neg c \wedge R(c, V) \wedge T(V, V') \wedge R(c, V')) \rightarrow \text{RF}(V) \geq \text{RF}(V') + 1$$

These two constraints allow for many different interpretations of  $\text{RF}$ . Every such interpretation satisfies our requirements and it is sufficient for such set to be non-empty. The well-foundedness of  $\text{Rank}$  implies, by Eq. (A.6), that  $\neg c \wedge R(c, V) \wedge T(V, V') \wedge R(c, V')$  is well-founded. Therefore, there must exist some  $V$  such that  $\text{RF}(V) = 0$ : in particular all the states in  $\neg c \wedge \neg R(c, V)$  and all the states in  $\neg c \wedge R(c, V)$  for which  $T$  does not admit any successor in the same region. Since  $\neg c \wedge R(c, V) \wedge T(V, V') \wedge R(c, V')$  is well-founded it

cannot allow for any infinite chain of states, hence it cannot allow any loop of states. Therefore, the constraints above do not contain any circular dependency in the definition of the assignments to the  $\text{RF}(V)$  and there exists at least one interpretation for  $\text{RF}$ .

We now show that  $fnl$  satisfies all hypotheses required by Def. 1.

**F.1** follows directly from Eq. (A.4) and the fact that  $\text{RF} = \mathbf{0}$  implies that  $T$  does not admit any successor in  $\neg c \wedge R(c, V)$ , hence it must admit some successor in  $c \wedge R(c, V)$ , which by definition is in  $D$ .

**F.2** By construction  $S$  contains all states of  $\exists c : R(c, V)$ . Eq. (A.2) ensures that this is an invariant, hence Hyp. F.2 holds.

**F.3** By construction,  $\text{RF}$  assigns decreasing integers to the chains described by the relation  $\neg c \wedge R(c, V) \wedge T(V, V') \wedge R(c, V')$ . Therefore, at every such step  $\text{RF}$  must decrease and Hyp. F.3 holds.

**F.4** Eq. (A.2) and the well-foundedness of  $\neg c \wedge R(c, V) \wedge T(V, V')$ , ensures that from a state in  $\neg c \wedge R(c, V)$  in a finite number of  $T$  steps we must reach a state in  $c \wedge R(c, V)$ . We defined  $\text{RF}$  such that  $\text{RF} = \mathbf{0}$  in the states whose  $T$  successors are in  $c \wedge R(c, V)$ , hence in  $D$ . Therefore, Hyp. F.4 holds.

We now show that  $fnl$  is a funnel-loop: it meets all hypotheses of Def. 2

**FL.1** trivially holds since  $fnl$  is the only funnel.

**FL.2** We defined  $S$  as the union of  $c \wedge R(c, V)$  and  $\neg c \wedge R(c, v)$  and  $D$  as  $c \wedge R(c, V)$ . Therefore  $D \rightarrow S$  and Hyp. FL.2 holds.

Finally, we show that this funnel-loop represents at least one fair path of  $M$  by showing that it meets all hypotheses of Th. 1.

**FF.1** holds since Eq. (A.1) ensures that  $R(c, V)$  has a non-empty intersection with the initial states  $I^M$ .

**FF.2** holds since Eq. A.5 ensures that every state in  $c \wedge R(c, V)$  satisfies  $F^M(V)$ . We defined  $D \doteq R(\top, V)$ , hence  $D \rightarrow F^M$  and Hyp. FF.2 must hold.

**FF.3** follows directly from Eq. (A.3).

□

#### Appendix B.6. E-CHC encoding of funnel-loop search is complete

**Theorem 8.** *Let  $floop$  be a funnel-loop of length one for a transition system  $M \doteq \langle V, I^M, T^M, F^M \rangle$ . Then, there exists an interpretation for the query symbols  $R, T$  and Rank satisfying all Eqs. (A.1)–(A.7).*

*Proof.* Given a *floop* of length one, we define an interpretation for the query symbols  $R$ ,  $T$  and  $Rank$  for the E-CHC. Let  $fnl \doteq \langle S, T_{fnl}, D, RF \rangle$  be the funnel of *floop*. By Th. 1 there exists a finite sequence of states  $\pi$  such that: it starts from an initial state of  $M$ , follows the transition relation of  $M$  and ends in a state in the source region  $S$ . Without loss of generality we assume  $\pi$  does not contain any state in  $S$  other than the last one. In the following we write  $\pi(V)$  for the predicate that holds iff  $V$  is in  $\pi$  and  $\pi(V, V')$  for the predicate that holds iff  $V$  and  $V'$  are two consecutive states in  $\pi$ . We define the interpretation for the queries as follows: (i)  $R(c, V) \doteq (\pi(V) \vee S(V)) \wedge (c \leftrightarrow D(V))$ , (ii)  $T(V, V') \doteq \pi(V, V') \vee (S(V) \wedge T_{fnl}(V, V'))$  and (iii)  $Rank(V, V') \doteq \pi(V, V') \vee RF(V') < RF(V)$ . We now show that this interpretation satisfies all Eqs. (A.1)–(A.7).

Eq. (A.1) By construction  $\neg c \wedge R(c, V)$  contains all states in  $\pi$ . By hypothesis, the first state of  $\pi$  is an initial state of  $M$ . Therefore, Eq. (A.1) holds.

Eq. (A.2)  $R(c, V)$  contains all states of  $\pi$  and of  $S$ .  $T$  either follows the transitions of  $\pi$  or, once it reaches  $S$  follows the transition relation of  $fnl$ . By hypotheses F.2, F.4, FL.1 and FL.2 such transitions must remain in  $S$ . Therefore, from every state not in  $S$  and not in  $\pi$   $T$  is false and the left-hand-side of Eq. (A.2) is false; otherwise, every  $T$  transition must remain within  $R(c, V)$  and Eq. (A.2) is true.

Eq. (A.3) Every step in  $\pi$  is also a step in  $M$  and by Hyp. FF.3 every step of *floop* underapproximates the transition relation of  $M$ . Therefore,  $T(V, V')$  underapproximates  $T^M$  and Eq. (A.3) holds.

Eq. (A.4) Since Hyp. F.1 must hold for  $fnl$  and every state in  $\pi$  must admit a successor until a state in  $S$  is reached, by construction  $T(V, V')$  always allows from some successor state in each region  $R(V, c)$ . Therefore, Eq. (A.4) holds.

Eq. (A.5) By Hyp. FF.2 the destination region  $D$  underapproximates the fair states. By construction  $c \wedge R(c, V)$  is equivalent to such region. Therefore, Eq. A.5 holds.

Eq. (A.6) holds by construction of the interpretation for  $Rank$ .

Eq. (A.7) holds since  $\pi$  is a finite sequence of states and each RF is a ranking function with respect to  $T_{fnl}$  and the corresponding  $S$ .
